As a Prominent Attorney Sees It—The prevailing multiple standard statutes put the cart before the horse. They have been framed under the high pressure of selfish, thoroughly organized, extravagantly paid lobbies of one idea and one purpose that persistently throng legislative chambers and propagate error, seeking means for their own profit through improvident legislation, substantially unopposed by any sufficiently organized rival force devoted zealously to supplying to legislators correct information upon the serious subjects involved. The ill-prepared doctor who becomes the champion of low standards is commonly engaged in trying to perpetuate his existing means of livelihood without further preparations, and, therefore, spends his money lavishly, devotes all of his time if necessary, and fights hard to win. The skilled doctor who becomes the advocate of reasonable standards is commonly working against his own interest, impelled by an earnest desire to protect the public health and to make his profession honorable, learned, and efficient. But the issue does not involve his bread-and-butter pursuit. He, therefore, presents his information, offers his advice, and departs. His adversaries stay on the job.—H. E. Kelly, Chicago.

The nurse inspects the child, no longer to find defects, but rather to find the normal, and if not normal to find out why and seek a way to attain normality.—Elnora E. Thomson, R. N. (Pacific Coast Journal of Nursing).

"Physicians, with the same justification that urged them to sponsor health safeguards, may object to health departments arrogating to themselves the field of private practice," says the Ohio Medical Journal editorially. "Health departments were established to safeguard public health and educate the public. Health departments were not established to furnish wholesale medical service to the general public, whether it be diagnostic, treatment, or after care.

"The diagnosis, treatment, and after care of patients is the duty of the private physician. Such is the field of private practice. Encroachments upon this field by health agencies is a step in the wrong direction and one which eventually will augur to the discredit of the health department through a loss of popular support of its policies.

"When the private field of medical practice is invaded by government, free medical service is rendered. There is no more reason for this than free groceries, hardware, or a thousand other material things which life demands. Recognized exceptions are, of course, proper educational health efforts and care of the indigent and public wards."

"Public opinion is today perhaps more critical of physicians than at any time in the past, not excepting Molière's day," says David Riesman (A. M. A. Bulletin). "Even some of the leaders in medicine are saying harsh things, to my mind not quite justified, of the rank and file of our profession. Our work is being scrutinized; we are held answerable in many directions.

Choice of Physicians by the Employe—The question whether the employer or the employe shall have the

right to choose the physician has no essential relation to the theory underlying the workmen's compensation acts. The expense of treatment can be equally well charged to industry and ultimately paid by the consumer, no matter who makes the choice. Presumably, the workman who has freedom of choice will procure the best medical services available, and no one has ever yet proposed that, in the exercise of his right to choose, the workman shall be debarred from choosing any medical service the employer may provide. The employer, then, who insists that the workman shall not be given freedom of choice is in the position of contending: (1) That the workman is willing to submit himself knowingly to inferior medical treatment in order to obtain the services of a physician whom he believes is not biased in favor of the employer; (2) that the workman is too stupid to choose the best service even when it is placed before him, or (3) that the service offered by the employer is not the best, but must be forced by law on the unwilling employe. As a matter of fact, to allow injured workmen to choose between the medical service offered by an employer and the medical service obtainable elsewhere should stimulate a healthy competition for excellence of service in the plant and among competing physicians, and thus result in the maintenance of the highest possible grade of professional services in the community.—W. C. Woodward, M. D. (A. M. A. Bulletin).

Physicians on Compensation Commissions—The decisions of most commissioners or deputy commissioners who are not physicians will frequently reflect their lack of medical knowledge.

To remedy this situation, the compensation commission must have one medical member. Until such time as adequate remuneration is paid by the state for such service, this may be hard to accomplish, but it should be insisted on by the various state medical societies; and when proper medical relations are established between the employer and the employe, and with the compensation commission, inadequate legislation can of a certainty be corrected.—L. H. Childs, M. D. (A. M. A. Bulletin).

Life Insurance Without Medical Examination—Because, it is said, of improvements in health of its policyholders, the Prudential Insurance Company is now considering applications, without medical examinations, for additional ordinary insurance, on the life of any policyholder up to and including 45 years of age, on whose life an ordinary policy has been issued at standard rates with full medical examination within twelve months prior to the application for new insurance. The amount may be up to \$10,000, but must not exceed the amount of the preceding policy, except where it was for only \$1000. In that event the new policy may be for \$2000. This concession also applies to policies on the lives of women.

District of Columbia Gets Disease Control Law—After five years of legislative history the venereal disease control bill for the District of Columbia was signed by the President on February 26. In spite of the fact that the bill has been on the verge of enactment at several times in the past, it did not become law until the closing days of the last session of the Sixty-eighth Congress, although every state in the Union has had some sort of a venereal disease control measure since 1921. The fact that sentiment for the Gilbert bill persisted for so long a time in the face of repeated legislative delays goes to show that the need for such a measure was keenly felt by residents of the District.

Under the provisions of the law, the chief officer of every hospital, dispensary, sanitarium, and penal institution must report to the health department cases of venereal disease as soon as they are discovered. The judges of the juvenile and criminal courts must report any persons appearing before them who are suspected of being venereally infected. Private physicians are required to make a similar report within ten days after a case has come under their control. The District law provides that these reports be kept confidential by the health officer and his agents. According to the Division of Venereal Dis-

eases of the United States Public Health Service, all of the states now have regulations requiring such reporting of cases of venereal disease.

In common with the regulations of thirty-five states, the District act provides that prostitutes, keepers of disorderly houses and persons convicted of any sexual crime are presumed to be a source of infection and are subject to examination. The health officer is required to employ for the protection of public health all such regulatory measures as may be necessary to prevent the spread of these diseases. He is also required to use every available means to ascertain the existence of venereal disease and the source of the infection. Persons against whom there is no criminal charge, but who are reasonably suspected of being infected, may be examined by the health officer upon consent of the parties. If, however, such persons withhold consent, an examination may be ordered by the court. A violation of such an order by continued refusal is punishable as contempt of court. In forty-three of the states the health officer is given express power to quarantine persons known to be infected with venereal disease. Nine of these states go even further, allowing the officer to placard the premises under certain conditions.

Twenty-nine states have laws which prohibit the advertising of preparations for the treatment of venereal diseases in lay publications, or which prevent the sale of such medicine to a lay person except on the prescription of a licensed physician. A like clause exists in the District law. Nineteen states have found it advisable to regulate the employment of the venereally diseased, and in the District of Columbia the law prohibits persons suffering from venereal disease, in a form likely to be a source of infection to others, from being employed as barbers, masseurs, cooks, bakers or other producers or handlers of food or drink, or from working in any other occupation in which the disease might endanger the public health.

Under the new law, it is compulsory upon physicians to advise their patients as to measures which they should take to prevent the spread of these diseases. They are also required to report all of the indigent cases which may come to their notice. The board of health is under obligation to take care of such cases and to see that they are given the proper treatment according to approved standards. Practically all of the states have some way of taking care of such indigent cases.

Four Recovered Lepers Discharged From National Leprosarium—The conditions under which lepers are released from this institution are exceedingly rigid. They require special observation for a period of one year, including monthly bacteriological examinations, to show that the leprosy bacillus is absent from the tissues. Certification of cure is also required from a board of three medical officers stationed at the hospital and experienced in leprosy.

The treatment at Carville includes the use of chaulmoogra oil, special preparations of mercury used intravenously, x-ray therapy, surgery of superficial areas of involvement, hydro-therapy, and the violet ray. The results of treatment have been sufficiently encouraging at this institution to induce numerous other patients, of whom there are believed to be several hundred in the United States, to agree to their transfer. A special car fitted up for the purpose, and carrying a doctor and a nurse, was used in the transfer last week of eleven patients from Florida, and seven were brought from California. There are at present 236 leper patients at Carville.

Good Advice—Do not get too deeply absorbed, to the exclusion of all outside interests. Success in life depends as much upon the man as upon the physician. You are to be members of a polite as well as of a liberal profession, and the more you see of life outside the narrow circle of your work, the better equipped you will be for the struggle.—Osler.

Medicine Before the Bench

Findings and Comments of the Courts on Acts and Omissions of Doctors

(EDITOR'S NOTE—*The law reports contain many interesting decisions, involving the reputations and fortunes of doctors. In this column in each issue a brief summary of one or more decisions and comments of the several courts of last resort upon the cases will appear. The matter will be selected by our general counsel, Hartley F. Peart, who, with Hubert T. Morrow, attorney for Southern California, will contribute from time to time.*)

In a comparatively recent decision the plaintiff, a child of 5 years of age, brought suit against a physician claiming that he had negligently diagnosed her condition and applied improper treatment. It appeared that plaintiff had sustained a fall, by reason of which a fracture to the hip resulted. The bone of the leg near the ankle-joint was also split. A few days later it developed that plaintiff was also suffering from osteomyelitis. The defendant failed to discover the fracture to the hip, but applied tight bandages and a cast on the fractured ankle. The plaintiff alleged that defendant "unskillfully placed said limb, which was then sore, swollen, tender and inflamed, in a plaster of paris cast and negligently made the same so tight as to greatly impede and stop circulation; that because of said treatment mortification set in, and a septic condition and blood poisoning resulted, extending throughout her whole body," making subsequent operations necessary to save the plaintiff's life. A verdict was rendered by the jury in favor of the plaintiff, and upon appeal therefrom the court in affirming the judgment said:

"It is the duty of a physician or surgeon to use that reasonable care and diligence ordinarily exercised by members of the profession in similar cases under like conditions, and failure so to do constitutes negligence on his part.

"... In other words, the implied obligation of the physician or surgeon to his patient is that no injurious consequences shall result to him from want of proper learning, skill, care, and diligence."

With respect to the contention of the defendant physician that since he was highly trained in his profession and, in fact, possessed all the necessary care and skill qualifying him to practice his profession, the verdict could not stand, the court continued:

"The question of negligence, or failure to exercise ordinary skill and care in the treatment of any particular case does not depend upon the professional skill and learning of the physician, but is to be determined from a consideration of his acts, conduct, omissions, and treatment in the particular instance. If he possessed the highest degree of skill and learning in his profession, and failed to exercise the care and diligence required by the law in treating his patient, his skill and learning could not shield him from the consequences of such negligent treatment. On the other hand, if he did not possess the skill and learning required by the legal standard, but his treatment in the particular instance was proper, he could not be held liable for the want of such skill which resulted in no injury to the patient. . . .

"We have examined the questions presented in relation to the evidence and instructions given and refused, and find no reversible error. The judgment is affirmed."

Bryan to the Contrary Notwithstanding—The moral principle inherent in evolution is that nothing can be gained in this world without an effort; the ethical principle inherent in evolution is that the best only has the right to survive; the spiritual principle in evolution is the evidence of beauty, of order, and of design in the daily myriad of miracles to which we owe our existence.—Henry Fairfield Osborn (The Forum).

Physicians' Sterilizers

Every Doctor's office should be equipped with proper sterilizers.

Illustrations show two of the many styles we carry for Sterilizing water and instruments. All our sterilizers can be heated by gas or electric current.

MEDICAL STRAWS

By THE EDITOR

Experience is fallacious and judgment difficult

THERE is another problem that confronts us, and those of you who are medical editors, mentors of our profession, must seriously consider it. In the Workmen's Compensation Acts, something has been introduced that is most unfortunate, and that is *taking away from the patient the liberty of choice of his doctor*.—President-elect W. D. Haggard (A. M. A. Bulletin).

GROWTH in character depends very much on our use of leisure, our way of escape from the dusty and weary walk of ordinary life, and so we need to retain in our hours of release from the prison of the external present all that may help us to understand the real significance of life, its mystery and its beauty.—British Medical Journal.

IN ESTABLISHING and maintaining medical ideals, we must be careful to separate them entirely from various cantos or obsessions which are so ready to obstruct progress.

THE medical officer of health should be the real as well as the nominal head of his department, and he should not be subjected to interference or supervision on the part of any other officer and should deal only and directly with the local authority and its committees.

SCIENTIFIC infant-feeding and pseudo-scientific feeding are not synonymous; but some people make themselves believe so.—Nebraska Medical Journal.

“WE HAVE one United States Senator who believes Mrs. Eddy was a deity,” says J. E. Dildy (Texas Medical Journal). “The banker carries an Irish potato for rheumatism; the congressman signs the Tan-lax ad., while the legislator votes for the chiro and “totes” buckeyes for piles.

“MANY persons think that education is something that we may give a child,” says Angelo Patri (Liberty). “No power on earth can do that. Education is something that a child must take. He takes it up from the earth and transforms it into intelligence by the experiences that he gathers through his nerves and muscles—and his hands.

“THE doctors of a community can tell the people what to do in order to prevent disease, but they are powerless to enforce their advice,” says the Long Island Medical Journal.

THE New York State optometrists are advocating a law that will compel physicians to pass the optometry board before being permitted to examine for and correct errors of refraction. In their official weekly they say, “The harder you make it for the medical doctor to invade our field, the less competition you will have.”—Indiana Medical Journal.

Why Quackery?—

There is no fool whate'er the sex or grade
But has his name among wise Doctors placed
And thus through greed the Healing Arts disgraced.
—Regimen Sanitas.

EVERY physician of an inquiring mind, wherever he may be located, can readily find all about him numerous medical problems of importance which he can help to solve.—C. M. Jackson, National Research Council.

Saving Animals by Vivisection—More than 200,000 dogs in the principal cities of Japan have been vaccinated against rabies. Not one of them has since taken the disease, although the malady is common among unvaccinated animals.—Colorado Medicine.

What would the antivivis do for these poor suffering animals?

PUBLIC health lies at the foundation, the very foundation of all human welfare. Unless that is conserved and protected, there is very little use in any other activity for the promotion of public welfare.—Calvin Coolidge.

There are about 1200 women physicians in Japan.

And He Won Fame—“The lancet and purge, consisting of senna, cassia, rhubarb, and syrup of pale roses, constituted the entire therapeutic armamentarium of Guy Patin, who won fame during the seventeenth century, ‘the farce-comedy era of medicine,’” says the Medical Journal and Record.

Three hundred years later the Guy Patins are still winning notoriety and fortunes by substituting the hypodermic needle for the lancet, “publicity” for the purge, and squashed goat glands purchased at a slaughterhouse for a few cents a pound for the “syrup of pale roses.”

THE difference between an educated doctor and an uneducated one is, the educated doctor knows when he doesn't know and the other one does not.—Journal Kansas Medical Society.

CHRISTIAN SCIENCE, as defined by W. H. Mallock: “A few fragments of science imperfectly understood, obscured by a few fragments of Christianity imperfectly remembered.”

Now Look at It—“When all government, domestic and foreign, in little as in great things, shall be drawn to Washington as the center of all power, it will render powerless the checks provided of one government on another, and will become as venal and oppressive as the government from which we separated.”

“I WOULD make health contagious instead of disease,” said Robert Ingersoll, when asked how he would improve on the work of the Lord.

A lot of people and some organizations are now claiming to be the authors of this slogan. Well, Ingersoll doesn't care.

“You can prevent typhoid by boiling your drinking water, or typhus by boiling your underwear, but neither form of cleanliness is of any avail against other diseases. Public sanitation will prevent hookworm, and draining the swamps will combat malaria, but none of these methods has the slightest effect upon smallpox.”—Medical Standard.

There are no safe generalizations about disease.

“Many people, especially those who cannot think for themselves and yet are under the professional necessity of speaking for others, imagine that a *point of view* is the *scene* itself. It isn't.”—Dearborn Independent.

PRISON is the easiest place in the world to reform from a distance.—Ex-Warden Johnson, (Commonwealth Club).

“No undisciplined man ever did any sustained toiling, no undisciplined man ever made any real sacrifice,” says a writer in Red Book.

Instruction in methods of physical and mental discipline constitutes an important responsibility of the physician. To be a worthy instructor he must practice self-discipline with fervor.

Complete asepsis possible with Castle sterilizers

Minor surgical cases and some treatment work must be conducted with complete asepsis.

Is this possible with your present office equipment? Most any sterilizer will sterilize, but a CASTLE goes farther; it virtually guarantees an unbroken sequence in your aseptic technique.

Take for example the instrument sterilizer on the No. 1316-A shown here. The combined tray and cover lift allows instruments to be removed without contaminating them on your hands. Also in the water sterilizer *all* the water is boiled *continuously*, and there is no unsterile water in the gauge glass.

BOOK REVIEWS

This column is conducted solely in the interests of California and Western Medicine readers. Critical comment, favorable and unfavorable, purely from the standpoint of the interests of the medical reader, will be made about books selected from the larger number acknowledged in the Books Received column. The advertising columns are open to book publishers who wish to make additional statements about their publications.

Gynecology. By William P. Graves. 3d ed. 936 pages. Illustrated. Philadelphia and London: W. B. Saunders Company. 1923.

This splendid textbook has been recently revised. Graves has added numerous new and excellent photo micrographs equally valuable to teacher and student. Tumors of the ovary have been reclassified, and include implantation tumors recently described by Sampson. The histogenesis of ovarian dermoids has been greatly clarified. Radium treatment in all of its applications has been clearly discussed. Ovarian transplantation and uterine transufflation are given in detail. Several new operative procedures, such as operations for prolapse of the urethral mucosa and for tubal sterilization have been added. In short, the book abounds with new information. It seems needless to say that Graves' Gynecology is one of the most valuable textbooks in this specialty. The book speaks for itself.

L. A. E.

Management of Diabetes. Treatment by dietary regulation and the use of insulin. By George A. Harrop. 176 pp. New York: Paul B. Hoeber. 1924. Price, \$2.

This book is a very well arranged, concise manual presenting the main features in the management of the average diabetic with diet and insulin. It is based on a series of fourteen lectures given to physicians and dieticians at the Presbyterian Hospital, New York, in the summer of 1923 during the infancy of insulin treatment.

The work presents only sufficient theory to make the practical applications well understood. General principles in diabetic metabolism are first presented, followed by chapters on the action and administration of insulin, including important descriptions and treatments of overdos-

Hunting With the Bow & Arrow

BY DR. SAXTON POPE

An attractive volume containing 256 pages and 50 illustrations, printed on art paper, substantially bound in buckram with stiff board covers and crash russet sides appropriate to outdoors. There are sixteen chapters, each dealing with some phase of archery. They describe the Indian methods of using the bow; how to make bows and arrows; the ballistics of archery; how to shoot; hunting small game—the coon, fox, coyote—and relate experiences in killing deer, mountain lion and bear with bow and arrow. The illustrations are from photographs taken in the field and give the reader a clear picture of the hunting scenes. It is a book that every archer and sportsman should have in his library and should be read by all who love this fair sport and adventure.

BOOK REVIEWS

(Continued from Page 493)

age with insulin. The chapters on the dietary management and insulin regulation are brief but very clear, and give a safe outline to follow in most cases. The practice of giving insulin in three doses daily is not general, however, and the majority of cases are now handled with only two daily injections. The complications of diabetes are briefly dealt with, and sufficient laboratory technic is given for adequately following the important laboratory side. The chapters on diets and food values are the least lucid in the book, but many valuable recipes are given. The book is the clearest brief manual of diabetes for the physician we have seen. D. E. S.

Fractures and Dislocations. Immediate management, after care, and convalescent treatment, with special reference to the conservation and restoration of function. By Philip D. Wilson and William A. Cochrane. 789 pp. Illustrated. Philadelphia and London: J. B. Lippincott Company. 1925.

A new fracture book, if it is to have an excuse for being, must be a good one. Wilson and Cochrane's book is good. It is simple, straightforward, and furnishes such accessory information (on anatomy, neurology, etc.) as may be needed in practice. It is written for the general practitioner, and the general practitioner will appreciate its compendiousness, which will save him much hunting about in other books for details he will wish to know.

While everyone may not agree with all its statements—and indeed it is impossible to write a book of practice with which everyone will entirely agree—no one can go wrong who follows the methods laid down by Wilson and Cochrane.

The illustrations are good, and there is enough bibliography to enable those interested to follow a given subject further.

We know of no book on fractures so handy, so clear, and so sensible. L. E.

X-rays and X-ray Apparatus. An elementary course. By John K. Robertson. 228 pp. Illustrated. New York: The Macmillan Company. 1924.

The subject matter is presented in clear, simple language, making it easily comprehensible to those with but a slight knowledge of physics. It is an excellent compact treatise, covering the essential physical principles utilized in the field of radiology. I. S. I.

Menace of Poorly Fitted Spectacles in Old Persons
—John J. Morton, New Haven, Conn. (Journal A. M. A.), stresses the fact that poorly fitted spectacles can be a real menace to their wearers. This is especially applicable in those beyond middle age, and the danger is considerably increased when senile changes have taken place in the skin of the irritated area. One should be mindful of this possibility and should take every precaution with the proper adjustment of eyeglasses. The places where constant abrasions are to be avoided are the bridge of the nose, the sides of the bridge near the inner canthi, the temples, and at the back of the ears. In the four cases reported by Morton, the temples were affected in three instances, and the fourth lesion occurred behind the ear. Owing to the tendency for basal cell cancer to occur most commonly on the nose, it is probable that most growths arising in irritation from spectacles will occupy this position. It would seem a priori that spectacles of the pince nez type would be especially liable to cause trouble, but no data are available to support this assumption. In view of the possibility of malignancy occurring in an irritated area, one should take the responsibility of impressing on patients the necessity of promptly attending to any maladjustment of their spectacles.

The Pathologist of 1940—Discussing the pathologist of the future, William C. McCarthy, M. D., says (Journal Lab. and Clin. Med.): "In the hands of the best clinicians we find, in a series of 60,645 patients, there were 225,785 laboratory reports (5650 metabolic basal rate determinations, 11,946 gastric analyses, 192,739 urinalyses and other laboratory procedures, 2021 electrocardiographic records, 13,964 fresh tissue examinations during operations and for purely diagnostic purposes, and 465 necropsies). These required time, material, space, and human energy. What percentage of these were of actual positive or negative value. How many of them would have been necessary in the hands of clinicians who were also well trained pathologists or pathologists who were keen observers of signs and symptoms."

Physicians & Surgeons Institute of PHYSIO-THERAPY

If its for the physician, hospital or sickroom, we have it

Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in—

ALQUA WATER contains the alkaline salts found normally in the human body. Physicians will find it invaluable where alkaline treatment is indicated. Not only is it very effective in the treatment of most acute and chronic diseases caused or accompanied by acidosis, but it is an ideal preventive, in that it neutralizes destructive acid by-products in the system.

GLACIER SPRING WATER with which Alqua is prepared, originates in the upper glaciers of Mt. Shasta, California, U. S. A., (Elevation 14,442 ft.) Its great purity without artificial treatment, renders it especially suitable for affinitization with the added salts, thus forming a combination that is remarkable as an alkaline water. Glacier water is released from the earth at Shasta Springs where it is put into black-tin lined carriers and transported to the Company's laboratory where the alkaline salts are scientifically added under the directions of an expert chemist, thereby creating, through the united efforts of science and nature, the wonderful medicinal virtues of Alqua Water.

ASK YOUR PHYSICIAN ABOUT IT.

The Management of an Infant's Diet

Constipation

One of the many advantages that may properly be claimed for Mellin's Food as a milk modifier is particularly emphasized by bowel movements normal in consistency and regularity.

Babies whose diet is prepared with a sufficient amount of Mellin's Food to thoroughly modify the quantity of milk necessary for the daily nutritive requirement receive food capable of normal digestion and assimilation and are therefore not troubled with constipation or disturbances caused by faulty elimination of waste matter.

Literature based upon evidence of many years' accumulation is ready for physicians who are interested. In making requisition, please ask for "Constipation" pamphlet.

Mellin's Food Co., 177 State Street Boston, Mass.

FRENCH HOSPITAL

French Mutual Benevolent Society, founded in 1851

Geary Street at Fifth Avenue

San Francisco, Calif.

General hospital of 220 beds, accepting all cases except mental diseases. Built upon the pavilion plan, allowing large air space for each patient. The buildings occupy a full city block, built around a beautiful central court. Aseptic, operating and delivery rooms. Complete X-Ray Department with portable apparatus. Eye and Ear, Genito-Urinary Clinics. Modern Hydrotherapeutic Department, etc.

Accredited for Intern training by the American Medical Association.

ACIDOSIS

By some investigators ACIDOSIS has been designated as a diminution of the alkalinity in the blood; by some as an excess of acid in the blood; by others as a lessening of reserve supply of fixed bases in the blood.

If the acid combining power of the blood is impaired BY A LACK of the alkalies, sodium bicarbonate and sodium phosphate, and may be built up by the process of food ingestion, *may we ask* attention to CALSO WATER, which is rich in the potential alkalies.

BANNING, CALIF.

Value of Electrothermic Methods in Treatment of Malignancy—Electrothermic methods are described by Grant E. Ward, Baltimore (Journal A. M. A.), that are said to be effectual in removing benign and malignant accessible tumors in a large percentage of cases. Electrodesiccation and electrocoagulation complete a quadrangle of therapeutic agents to be used in the treatment of accessible malignancy. Surgery, roentgen ray and radium are all essential, but fall short often. Desiccation or coagulation in combination with one of these methods adds the much-needed facilities in the successful treatment of cancer. As technic is perfected and experience is enlarged, the percentage of cures and good palliative results will be greatly increased by combining these methods. The newer electrothermic machines are much more powerful than those formerly used and give currents of greater range of intensity and quality, and at the same time are susceptible of more accurate control.

The best equipment for the nurse, outside of the simple technical and anatomical knowledge that must necessarily be part of her training, is a cheerful desire to serve, a tactful sympathy, and the ability and willingness to carry out the doctor's orders implicitly.—Samuel J. Kopetzky, M. D., President New York County Medical Society.

As He Sees Quacks—Inasmuch as even the intelligent person is rarely able to detect the falsity of the pseudo-scientific claims made by various cults, this society, and all others like it, must expose the fads and "isms" which arise—and do this not by arbitrary denunciation, but through a clear analysis of their fallacies.—Samuel J. Kopetzky, in his inaugural address as president New York County Medical Society.

Democracy has been afraid of itself, and of its own chosen officials, and has hedged them about with so many restrictions that genuine efficiency has been well-nigh impossible.—Frank O. Lowden.

ALUM ROCK SANATORIUM

FOR THE TREATMENT OF TUBERCULOSIS IN ALL ITS FORMS

The Sanatorium adjoins Alum Rock in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

CALCREOSE

R. RAMSDEN WADE reports (Brit. M. J. 1: 158, Jan. 24, 1925) having had good results from the administration of creosote in the treatment of cases of influenzal pneumonia and chronic influenza which are very liable to be mistaken for phthisis.

**POWDER—TABLETS
SOLUTION**

CALCREOSE (calcium creosotate) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime. It has the pharmacologic activity of creosote, but apparently does not have any untoward effect on the stomach.

POTTENGER SANATORIUM

FOR DISEASES OF THE LUNGS AND THROAT

Monrovia, California

AEROPLANE PICTURE OF THE POTTENGER SANATORIUM

Situated on the southern slope of the Sierra Madre Mountains at an elevation of 1000 feet. Winters delightful, summers cool and pleasant. Thoroughly equipped for the scientific treatment of tuberculosis. We have established, in connection with the Sanatorium, a clinic for the diagnosis and study of such non-tuberculous diseases as asthma, lung abscess and bronchiectasis.

Los Angeles Office: 1045-6-7 Title Insurance Building
Cor. Fifth and Spring Streets

For particulars address:
POTTENGER SANATORIUM,
Monrovia, California

BANKSIA PLACE SANITARIUM
FOR NERVOUS AND MENTAL CASES

Exclusive accommodations, cottages, rooms in suite with private baths. Complete hydrotherapy and electrotherapy. Situated in the beautiful foothills of Hollywood. Open to all reputable physicians. **Dr. G. S. HERBERT, Medical Director, 5227 Santa Monica Blvd., Los Angeles, Cal. Phone Holly 584.**

CIPHER WAFERS

Cipher Wafers are an attractive bread substitute to be used in cases of diabetes, constipation and obesity.

These wafers, which are made of washed bran and other non-nutritive substances, are made in five flavors and take the place of bread, crackers and cookies without adding any food value to the diet.

Plain with salt, plain with saccharine, vanilla, spice, are sold at \$.50 per 10 oz. package; cocoa nib at \$.60 per package. Postage extra. Other foods for special diets can be obtained by ordering from

The Cascade Washers and Extractors in the laundry of the Hospital for Joint Diseases.

The Hospital for Joint Diseases, 1919 Madison Ave., New York City. Architects: Buchman & Kohn. Consultant: Oliver Bartine.

“Complete in every detail”

*...the laundry of the Hospital
for Joint Diseases, New York City*

At the Hospital for Joint Diseases in New York City, a completely equipped “American” laundry is operated as a regular part of the hospital service. This laundry handles the bed linens, nurses’ uniforms, towels and various other articles with such speed and efficiency that the hospital is able to keep a smaller stock of linens on hand than would otherwise be the case. There is a distinct advantage, too, in having the important feature of hospital laundering directly under the supervision of hospital authorities.

The laundry is completely equipped to handle every detail of the hospital’s washing and ironing. It was designed and installed by engineers of The American Laundry Machinery Company and includes the following:

- 1—40 in. x 93 in. KF Disinfecter.
- 1—42 in. x 73 in. Monel Metal Cascade Washer.
- 1—36 in. x 33 in. Monel Metal Cascade Washer.

- 2—30 in. Extractors.
- 1—40 in. x 54 in. Vento Drying Tumbler.
- 1—Panel Control Board.
- 1—90 Gallon Soap Tank
- 2—3 ft. x 12 ft. Flat Work Tables.
- 1—Zinc-Covered Starch Table.
- 2—No. 38 Prim Presses.
- 1—No. 1804 Ironing Table.
- 13—No. 1802 Ironing Boards.
- 1—Starch Cooker.
- 1—110 in., 5-roll Extra “Floating Roll” Flat Work Ironer.

A corps of specialists maintained by The American Laundry Machinery Company will be glad to advise you in regard to your laundry problems. Their experience covers the installation of most of the hospital, commercial and institutional laundries of the United States and Canada. A card will bring you full details, without obligation.

Ask Your Fellow Practitioner Who Is Using Quartz Light

The great number of physicians, sanatoria and hospitals throughout the world who are using the ALPINE SUN and KROMAYER LAMPS, gives testimony to their value as a therapeutic adjuvant.

"The results that we get by using an artificial source of Ultra Violet Light are so marked, that sometimes we wonder . . ."
Quoted from J. A. M. A., Nov. 22, 1924, Vol. 83, No. 21, page 1637.

For literature and reprints of its use in Rickets, Tetany, Eye, Ear, Nose and Throat conditions, Tuberculosis (Glandular and Intestinal, etc.).

FOR THE PATIENT WHO BALKS AT BRAN

ZED

The same patient who registers a decided dislike for bran gladly takes to ZED. For ZED is a delicious laxative biscuit in which the coarseness of the bran is hidden by the fine flavor of whole wheat.

In addition, milk, natural fruit and vegetable extracts are used in the blending of ZED to make it tasteful and appealing—and also to supply important mineral elements.

Thus the patient with a marked antipathy to bran finds himself with a marked liking for ZED. There is nothing in ZED to remind him of that "straw-like" taste he has mentally associated with bran. There is everything in ZED to make him *like* to eat the amount you advise.

We will be glad to supply to any physician on request a full-sized package of ZED for trial purposes.

Zed Corporation • San Francisco

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of

them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) \$45.00 per week and upward.

Victor Quartz Lamps
For Correct Ultra-Violet Therapeutic Technique

The correct technique, which is so important a factor in securing the desired results in ultra-violet therapy, is definitely possible with Victor air-cooled and water-cooled quartz lamps. In their design and construction they so perfectly reflect the long experience gained by the foremost European and American specialists in ultra-violet therapy that they meet the practical conditions encountered in the hospital and general practitioner's office.

The Victor X-Ray Corporation has reprinted the principal, authoritative papers on ultra-violet therapy for the benefit of physicians who may not have access to the original sources. These important papers will be sent free of charge on request.

* 4½ Ounces to a quart of water

KLIM is completely soluble in water of any temperature

When Used in Infant Feeding

Reliquified KLIM at normal strength has the same analysis and caloric value as natural whole cow's milk and is subject to the same modifications when used in infant feeding

—milk, produced under the supervision of the New York City Department of Health, whose regulations compel, at each farm, examination of every cow once a year, maintenance of a properly equipped milk house, clean utensils, proper sanitary conditions, and milk maintained under 60 degrees F. until delivered to the Merrell-Soule Plant, where all equipment coming into contact with the milk—most of it glass-lined—is scalded clean daily. Complete laboratory control gives final assurance that nothing but a clean product, free from pathogenes, with a low bacteria count shall bear the name KLIM.

*Literature and samples
sent promptly upon request*

Recognizing the importance of scientific control, all contact with the laity is predicated on the policy that KLIM be used in infant feeding only according to a physician's formula.

When Sugar is Taboo

In cases where non-sugar diets are essential, Nutradiet canned fruits may be prescribed.

They are highest quality fruits — well-known S & W quality—packed *without syrup*. Sterile water or the natural fruit juice is used instead.

Hence Nutradiet fruits contain less sugar than the fresh fruit itself—a minimum of carbohydrates.—for a portion of the natural sugar is thrown off in the water, after the fruit is canned.

Write for chemical analyses. Also list of grocers selling Nutradiet fruits.

[[Nutradiet salt-free vegetables include a variety of vegetables packed without salt or sugar.]]

PREVENT HAY FEVER

Pollen Allergen Solutions Squibb

NOW is the time to immunize your Hay Fever patients against their annual affliction. Pollen Allergen Solutions Squibb are used for the prophylaxis and treatment of Hay Fever and other pathologic conditions due to pollen sensitization. Treatment should commence several weeks before the expected onset of the usual seasonal occurrence.

SQUIBB'S DIAGNOSTIC POLLEN ALLERGEN SOLUTIONS afford the means of determining the offending pollens as a guide for treatment. The prophylactic treatment consists of graduated doses of the glycerol solutions of the pollen proteins. Complete sets of these in graduated doses and in 5 Cc. vials are offered by the Squibb Laboratories as Pollen Allergen Solutions Squibb.

Write us direct for special information concerning the use of Diagnostic Allergens Squibb and Pollen Allergen Solutions Squibb for the prevention and treatment of Hay Fever and allied conditions.

INFANT DIET

MATERIALS

FEEDING THE AVERAGE INFANT

*The proper food for the infant is
Mother's Milk*

Complemental feedings of Fresh Cow's Milk, Water and Mead's Dextri-Maltose are very helpful to the infant's nutrition when the supply of Breast Milk is insufficient.

When Summer (Fermentative) Diarrhea is present, Mead's Casec will generally give gratifying results.

If Infant Diet Materials of quality are needed, MEAD'S products may be used with Confidence by physicians.

Samples of Mead's Dextri-Maltose
Samples of Mead's Casec

The Mead Policy

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians.

Doctor Are You Reading BETTER HEALTH?

MOST newspapers, magazines and publications of every sort are now featuring alleged Health Education, Public Health, and even the practice of medicine by mail, as one of their functions. Of the few magazines that are producing worthwhile informative publicity in this field, BETTER HEALTH is the oldest. This magazine is owned and conducted by physicians and devoted entirely to improving the knowledge of the general public on matters pertaining to the promotion, conservation and protection of health; and it is one of the exceedingly small number presenting sound and authoritative health information of the same general type that the physician gives to his patients and friends. A copy should be on the table in your reception room at all times. Every physician, at least in the Western States, should be a subscriber to BETTER HEALTH Magazine. It needs your support for many and obvious reasons. If you are not a subscriber, please cut out the coupon and mail it at once. Suggest to your patients that they also subscribe.

To BETTER HEALTH, Balboa Building, San Francisco

Please send me BETTER HEALTH, the monthly magazine with the Daily Health Service, beginning with the May issue, 1925. Upon receipt of magazine and bill, I will send you \$3, payment in full, for one year's subscription.

AMPOULES

[PARKE, DAVIS & COMPANY]

COMMEND THEMSELVES TO THE
CAREFUL PHYSICIAN

Because

(1) In them the element of chance is superseded by the certainty of science.

(2) They are ready to use and easy to carry.
No time is lost in making up solutions as required.

(3) They are made with full consideration of the characteristics of every ingredient. The glass employed is one which will not react with the solutions contained in them.

AMPOULES PRESENT AVERAGE SINGLE
DOSES OF IMPORTANT DRUGS

readily transferable to the hypodermic syringe, and less likely than improvised solutions to irritate the subcutaneous tissues.

The principle of standardization, which has given character to our products as a whole, is rigorously applied to the ampoule list, comprising a wide variety of formulae.

Of the line offered by Parke, Davis & Co., some are especially intended for intravenous use although, with very few exceptions, any solution in the list can be thus administered, the only desideratum being that which the physician alone can supply, namely, intravenous technique.

*Our 48-page, therapeutically indexed booklet

ILETIN INSULIN, LILLY

*Pure • Stable
Constant in Unitage*

Iletin (Insulin, Lilly) is supplied in containers of two sizes: 5 c.c. vials and 10 c.c. vials. Both the 5 c.c. and 10 c.c. vials bear the same designation: U-10, U-20 and U-40.

To distinguish between the two sizes it will be necessary, for example, to order as U-10 5 c.c. vials or U-10-10 c.c. vials.

In absence of specifications as to size wanted, the 5 c.c. vials will be supplied.

PITUITARY EXTRACT LILLY

Pure • Stable • Uniform in Strength

Purity—This extract contains the active principle of the posterior lobe of the pituitary gland in a state of purity not attained heretofore on a commercial scale.

Stability—It will remain active over a long period. Test lots have been boiled with but little loss of activity.

Uniformity—Special methods have been devised for bringing each lot to the same standard of strength.

Pituitary Extract, Lilly, is supplied in two strengths, obstetrical and surgical; order as follows:

No. 117—Obstetrical 1-2 c.c. Ampoules

No. 118—Obstetrical 1 c.c. Ampoules

No. 119—Surgical 1 c.c. Ampoules

These ampoules are packed six in a box, each in an individual carton.

Write for additional information.

All Lilly Products are supplied by the Drug Trade.

Petrolagar

(Reg. U. S. Pat. Office)

"HABIT TIME"

Creating the habit of a regular bowel movement is undoubtedly the most important factor in the treatment of constipation.

PETROLAGAR affords a method of establishing the normal function. In this emulsification of 65 per cent mineral oil with agar-agar, the action is entirely mechanical; the dosage can be gradually diminished and eventually discontinued.

In the bowel, the oil of PETROLAGAR is minutely diffused through the fecal mass, giving perfect lubrication and diminishing the possibility of leakage.

PETROLAGAR does not contain any fermentative gums. It is a mechanical emulsion which has a purely mechanical action on the bowel.

It does not establish the "cathartic habit," but replaces the habit-forming and irritating cathartics.

PETROLAGAR is issued as follows: PETROLAGAR (Plain); PETROLAGAR (with Phenolphthalein); PETROLAGAR (Alkaline); and PETROLAGAR (Unsweetened, no sugar).

It has been accepted for New and Nonofficial Remedies by the Council on Pharmacy and Chemistry of the American Medical Association.

Send coupon for interesting treatise on the physiology of the bowel, entitled "Habit Time." You may have a copy free, without obligation.

DR. J. B. MANNING, *Medical Director*
P. O. Box 507, Santa Barbara, California

Pulmonary Complications After Laparotomies—Anatole Kolodny, Iowa City (Journal A. M. A., March 14, 1925), points out that acute pulmonary complications after laparotomies are still encountered frequently. The clinical incidence of post-operative pneumonia is far greater after a laparotomy through the upper abdominal wall than after laparotomies when the incision has passed through the lower abdomen only. Pain in the operative wound during the first days after the operation forces the patient on whom a laparotomy through the upper abdomen was done to abandon the abdominal type of respiration. Hypodermoclysis under the pectoral muscles in such patients, with a trauma to the thorax wall sufficient to prevent an adequate deep thoracic respiration, results in an increase in frequency of the respiratory excursions, with a secondary rise infrequently of the pulse. To avoid this deleterious reaction of the hypodermoclysis in patients after laparotomy, infusion should be made in the outer aspects of the thighs.

Production of Liver Necrosis—Reuben Ottenberg and Harold A. Abramson, New York (Journal A. M. A., March 14, 1925), report on experiments undertaken primarily to determine the upper safe limits of dosage of tetrachlorphenolphthalein and tetrabromphenolphthalein. The doses needed to produce severe symptoms and liver lesions were enormously larger than those used in the tetrachlorphenolphthalein test for liver function (0.005 gm. per kilogram). While the amount of tetrabromphenolphthalein used for gall-bladder visualization (0.1 gm. per kilogram) is also safely below the toxic dose, the margin is not so large, and suggests the necessity of caution in cases in which the liver parenchyma is already damaged by disease.

"Mental Health"—Health of mind is of as much consequence to happiness and well-being as is health of body. A rational cycle of work, study, relaxation, and amusement is essential to the health of the mind."

"Simple" Goiter

A Surprisingly Prevalent Disease,
yet One of the Easiest to Prevent.

Iodostarine Tablets afford a method
of Prevention and Treatment logi-
cally suited to your private practice.

OUT OF 3,200 SCHOOL CHILDREN affected with simple goiter in one district, 2,780 (86.9%) were cured completely and 320 more (another 10%) were greatly improved after treatment with Iodostarine Tablets. (Steinlin: *Official School Journal of St. Gall*, 1922.) In other words, 3,100 out of 3,200 or 97% of these goiters responded to treatment—a notable achievement and an indication of the effectiveness of the remedy when properly employed in correctly diagnosed cases.

For Goiter prevention, Iodostarine Tablets are being widely used by physicians and Public Health Authorities. Reports show that they are likewise highly efficient in the treatment of simple goiter of adolescence.

Bear in mind, Iodostarine Tablets contain Iodine in an organic form; are absolutely definite in strength; are stable; keep indefinitely without liberating Iodine; do not cause gastric irritation; are very palatable.

*Boxes of 50 Tablets, Each Tablet Equivalent
to 10 mgm. Iodine*

If you are not familiar with the dosages of Iodostarine Tablet administration we shall gladly send you information and, if you so desire, a complimentary supply for trial.

This Letter Set Him to Thinking

"Dear Sir:

"I represent Mrs. ———, who is the mother of Mrs. ———, 3307 N. Albany Ave. Her daughter informs me that Mrs. ——— was injured in an accident January 27, 1923, caused from a fall.

"Mrs. ——— advises me that you started treating her mother for a bruise; that no X-Ray was taken and that you continued to treat her up to and including February 27, 1923. She then called a Dr. ——— to examine her mother's injuries, her mother at that time being in great pain, and Dr. ——— ordered her to a hospital, where an X-Ray was taken and showed a fracture. On account of neglect on your part, the injury became very serious, and after the setting of the fracture Mrs. ——— was compelled to and did remain in bed for several weeks, and up to the present time has not completely recovered from the injury.

"In view of the above circumstances, would you kindly let me know what your intentions are in this matter, in the way of repaying and compensating this woman for your alleged carelessness and neglect in treating her. Yours truly,

.....
"Attorney-at-Law."

And Then We Received This

"Gentlemen:

"For some months I have been receiving literature from your company offering to sell me protection against malpractice charges and damage suits. I put this off too long; for I have a suit filed against me.

"However, it is not too late to take protection against others that might be filed.

"Yours very truly,

.....

Unusual Complication Following Usual Operative Procedure for Varicose Veins—Two cases are cited by David Fisher and Edmund H. Mensing, Milwaukee (Journal A. M. A., March 7, 1925), which emphasize and strike home vividly the extreme importance of a careful investigation in so self-evident a condition as varicose veins. In one of the cases the man had been advised to have an operation for varicose veins before an ulcer developed. The physical examination was negative except for the extremities, which showed marked prominence and slight bulging of all the superficial veins, extending from both feet upward to a point about 8 cm. above Poupart's ligament. There was very little tortuosity. The leg was raised and drained of its blood, then constriction was applied to the saphenous opening, and the leg lowered. Even after ten minutes, the veins did not show any filling. This, of course, meant that the deep or perforating veins were thrombosed or varicose. In view of a history of typhoid, it was safe to assume that in this case the deep or perforating veins were thrombosed, preventing the filling of the superficial veins. Had this man been operated on, gangrene of the extremities would probably have resulted. In the second case an ill-advised operation was followed by gangrene necessitating a midhigh amputation. An entire extremity was sacrificed, not to mention the physical suffering in the interim, because of the failure in the first place to apply a very simple test to the circulation. The authors urge that in every case of varicose veins, the Trendelenburg test be applied to ascertain the condition of both the superficial and deep veins; and in case of doubt, when the collateral circulation extends above Poupart's ligament, and no intra-abdominal cause for venous obstruction exists, the deep veins should be suspected.

An Old Fact Restated—"Psychiatrists tell us that whatever goes into the brain by any other route than reason cannot be removed by reason."

MARY'S HELP HOSPITAL

145 Guerrero Street, San Francisco

Accredited for Intern Training by the American Medical Association.

Accredited School of Nursing.

Open to All Members of the California Medical Association.

Institutional Member League for the Conservation of Public Health.

A limited general hospital of 150 beds, owned by the Archdiocese of San Francisco, and operated by the Sisters of Charity. All classes of patients are admitted except those suffering from communicable or mental diseases. The hospital was organized and incorporated in 1892. All buildings were destroyed by the fire in 1906. A complete new modern hospital was finished July 2, 1912. Mary's Help Hospital is well located, well constructed, well arranged, and well equipped for good service.

Are You a Specialist?

Of course you are! You may be a "family doctor" of the good old variety—but nevertheless you are a specialist. You specialize in curing the physical [and sometimes mental] ills of humanity.

But the chances are you do not also specialize in business—investment securities—property values—collections and disbursements—the host of routine business details forced upon the attention of the professional man.

May we relieve you of the burden of those details? We are specialists. We can care for them at a lesser cost than you can yourself.

Bedtime Story—Once there was a man who was an ordinary clerk at \$14 a week. "There is no reason," said his friends, "why any man should be such a failure today." So at their suggestion he went to a psycho-analyst, took a course in personality development, subscribed for the American Magazine and Success, followed Bernarr Macfadden's health rules, and ate three cakes of yeast daily. That man is now making \$14 every week.—Life.

Hippocrates

The Hartung Hospital Silent Call Signal System
SAFE—SILENT—SIMPLE

Call Station No. 102

Fully Guaranteed
Trouble Proof

The calling station herewith illustrated shows one of the sixteen combinations that we have to offer.

This station consists of the control switch with ball chain, slip connector, pull cord and pear-shaped pendant attached. A slight pull on the cord illuminates a red lamp over the door in the room visible to the patient, over the door in the corridor, a red pilot lamp in the diet kitchen and utility room, and the lamp in the annunciator which shows the number of the room calling. These lamps continue to burn until the call is answered and the control switch knob restored to the off position by the nurse.

The push and pull Emergency Switch is used by the nurse only when she finds the patient in a critical condition and needs immediate assistance. The nurse, pulling out the button of the Emergency Switch, illuminates a green lamp in the corridor over the door of the room, a green pilot light in the superintendent's office, at the nurses' station and wherever desired. This Emergency call is restored, when answered, by pressing the button of the switch which extinguishes all the green lights. If desired an audible buzzer may be connected to the emergency switch.

As predicted at the beginning of the year, my business has doubled in amount so far this year over the same period of last year. The reason for this is without doubt in a great measure due to the service that I am enabled to give. Thirty years of experience with medical books, in every phase, including selling, manufacturing and editing, has given me the right to say that I know something of Medical Books. Let me help you solve your Medical Book problems.

Troy Service and Equipment meets fully the demand for laundry service in the better hospitals.

This letter from Dr. Hedden is conclusive proof that all claims made by us for our service and equipment are fully merited. We can perform the same satisfactory service for your institution, no matter where you are located.

1245 UNION AVENUE

MEMPHIS, TENNESSEE

November 13, 1924.

Troy Laundry Machinery Co.,
East Moline, Illinois

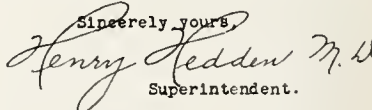

Gentlemen:-

Permit me to thank you for the very excellent service provided by your firm in the installation of our laundry equipment. Exactly three weeks elapsed from date of shipment until our laundry was handling the entire work of the Hospital

The machinery is all of the very best construction, and has given entire satisfaction from the first day. Your construction man, Mr. Heagle, is a very competent workman, and did an excellent installation job in record time. He helped us get our working force organized, and made a number of valuable suggestions to enable us to do high grade laundry work.

Our building was designed and built solely for laundry purposes, and with your equipment, makes the finest institutional laundry in this city, and I doubt very much whether there is a finer laundry of its kind and size in the country

The installation is already occasioning considerable favorable comment from laundry men here, and I think that your company could well point to it as a model selection of equipment and installation.

Sincerely yours,

 Superintendent.

Heart Station

A laboratory for the investigation of Cardiac conditions.

As we are equipped with highly specialized apparatus, in particular an instrument for determining the exact angle in which the patient is being examined, we believe we are enabled to give the heart and especially the Aorta a more than ordinary accurate examination.

An outline of our routine examination is as follows:

- (I) a. History.
b. Complete Physical Examination.
c. Heart Function Tests.
d. Kidney Function Tests.
e. Vital Capacity, etc.
- (II) X-RAY EXAMINATION
a. Pictures in Frontal Position.
b. Pictures at various angles.
- (III) FLUOROSCOPIC EXAMINATION
a. Study of the comparative size and shape of the different Cardiac chambers.
b. Measurement of the Anterior-Posterior size of the heart, frequently the first part to show enlargement.
c. Orthodiagram and Cardiac Pattern—the latter to be used in checking up your own physical findings.
d. An attempt to judge the quality of the heart muscle and determine its probable efficiency and reserve power.
e. Careful measurement of the Ascending and Descending Aorta.
- (IV) ELECTROCARDIOGRAPHIC STUDY
Almost indispensable as a diagnostic aid in many Cardiac conditions.
- (V) METABOLISM TESTS, ETC.
In all cases a detailed and comprehensive report is furnished which will include diagnosis, prognosis and suggestions.
No stay in the hospital is required.
Any single test or examination can be asked for.

Metaphen, D. R. L.

*A Powerful, Stainless,
Mercurial Germicide 500 Times
the Strength of Phenol*

METAPHEN IS STAINLESS

For Skin Lesions:

Metaphen is effective in the treatment of pyogenic skin conditions and skin affections caused by vegetable parasites.

For Gonorrhea:

Metaphen is of great value in most cases of acute gonorrhea. The urethral discharge is stopped in most cases after a few treatments.

For Sterilizing Instruments:

Metaphen does not tarnish instruments, even when the latter are immersed in a 1:1000 solution of the compound for one week or more. Immersion for a few minutes in 1:5000 solution will render the instrument, sterile. Surgical rubber goods are sterilized with equal rapidity.

For First Aid:

Metaphen is superior to Iodine in treating cuts and open infections and is without stain or damaging effect on the tissues.

*Ask for booklet describing
the many uses of Metaphen*

WHEN food does not feed—when even milk, the most nearly perfect of all nutritional foods, fails to nourish, it has been found that the addition of 1% of pure, unflavored, unsweetened gelatine to the milk overcomes the difficulty.

The protective colloidal ability of the gelatine, in preventing the coagulation caused by the enzyme rennin and hydrochloric acid of the gastric juice, will largely prevent stomach curdling and insure the complete assimilation of all the nutritional elements of the milk. Thomas B. Downey, Ph. D., of Mellon Institute, University of Pittsburgh, has clearly proved by a series of standard feeding tests that the addition of 1% of pure, plain gelatine, dissolved and added to milk, will increase the nutritional yield by about 23%. The approved formula is here given:

Soak for ten minutes one level tablespoonful of Knox Sparkling Gelatine in $\frac{1}{2}$ cup cold milk taken from the baby's formula; cover while soaking; then place the cup in boiling water, stirring until gelatine is fully dissolved; add this dissolved gelatine to the regular formula.

For children and adults follow the same method in the proportion of $\frac{1}{2}$ teaspoonful of gelatine to a glass of milk.

To safeguard against impurities and disturbing acidity it is essential to specify a plain, unflavored, unsweetened gelatine, such as Knox Sparkling Gelatine—the Highest Quality for Health.

A package of Knox Sparkling Gelatine, together with the physician's reference book of nutritional diets with recipes, will be sent free to any physician if he will write to the Knox Gelatine Laboratories, 417 Knox Avenue, Johnstown, N. Y.

D., Professor of Chemistry and Toxicology in the University of Iowa; Author of an Introduction to Chemical Analysis for Students of Medicine, Pharmacy and Dentistry, and Paul Reed Rockwood, M. D., Fellow in Medicine, the Mayo Foundation. Fifth edition, revised and enlarged. Illustrated with four colored plates and forty-three text engravings. Philadelphia: F. A. Davis Company, publishers. 1924.

Pseudo-Appendicitis. A Study of Mechanical Syndromes of the Right Lower Quadrant Simulating Appendicitis. By Thicrry De Martel, Chirurgien des Hopitaux de Paris, and Edouard Antoine, Medecin des Hopitaux de Paris. Authorized translation from the French by James A. Evans, M. D., formerly Assistant Radiologist, Hopital St. Antoine, Paris. Preface by R. Bensaude, Medecin des Hopitaux. Illustrated with forty-one engravings. Philadelphia: F. A. Davis Company, publishers. 1925.

Clinical Therapeutics. I, Therapeutic Agents; II, Therapeutic Procedures; III, The Treatment of Symptoms; IV, The Treatment of Diseases. By Alfred Martinet, M. D., Paris, France, with the collaboration of Drs. Desfosses, G. Laurens, Leon Meunier, Lomon, Lutier, Martingay, Mougeot, Saint-Cene, Segard, and Terson. Authorized English translation from the second revised and enlarged edition by Louis T. de M. Sajous, M. D., Associate Professor of Experimental Pharmacology, School of Medicine, Temple University; Instructor in Endocrinology, Graduate Medical School, University of Pennsylvania. With 332 text engravings. Complete in two royal octavo volumes: Volume I, Therapeutic Agents and Procedures; Volume II, Treatment of Symptoms and Diseases. Philadelphia: F. A. Davis Company, publishers. 1925.

A Textbook of Human Physiology, including a section on Physiologic Apparatus. By Albert P. Brubaker, M. D., Professor of Physiology and Medical Jurisprudence in the Jefferson Medical College; formerly Professor of Physi-

(Continued on Page 559)

---to you successful men of the profession who know that efficient skill comes only with long experience and specialization.

The Value of Experience

Theory and book-knowledge and scientific data are all necessary of course, but actual matter-of-fact experience is essential. It is *indispensable*.

Experience is the very foundation of theory and knowledge; the bed-rock on which successful careers are built.

For nearly twenty years our wholesale prescription business has been growing on the basis of experience and specialization. From the fullness of that experience you can secure a class of service not available elsewhere.

So right from your own professional practice you have a parallel by which to judge optical Rx work—and we welcome your judgment by that standard.

Specialization to us means one grade of materials and work, the best. It means confining our service at all times to the legitimate refractionist. We have no retail interests. Therefore are never competing with our patrons. Two vital points to remember.

RIGGS OPTICAL COMPANY

STRICTLY WHOLESALE EVERYWHERE

Radium and Oncologic Institute

1052 West Sixth Street

LOS ANGELES

RADIUM THERAPY

An adequate quantity of radium and complete emanation apparatus affords the facilities essential for modern technique in radium therapy.

DEEP X-RAY THERAPY

Two complete 300,00-volt installations providing every facility for preliminary and post-operative Radiation and X-ray Therapy alone or in combination with other treatment.

X-RAY DIAGNOSTIC LABORATORIES

Completely equipped offer the profession every assistance for roentgenology as an aid in diagnosis.

HOSPITAL AFFILIATIONS

Including a complete high voltage X-ray and Radium Therapy department in the Methodist Hospital amply provide for cases requiring hospitalization.

LABORATORIES

Affiliated for clinical and pathological study and complete facilities for Actinic Ray Therapy.

This institution possesses unexcelled facilities for radium and radium emanation therapy and high voltage X-ray therapy. With modern X-ray diagnostic, clinical and pathological laboratories, complete equipment for electric coagulation, cautery and allied surgery, it offers the medical profession unexcelled facilities for the diagnosis and treatment of neoplastic diseases.

We desire to confer and co-operate with the Medical Profession in the treatment of cancer and other appropriate diseases and request inquiries either in person or by correspondence.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.

2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.

3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.

4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.

5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

SPECIAL ARTICLE

THE BEGINNINGS OF CALIFORNIA'S MEDICAL HISTORY

By GEORGE D. LYMAN, A. B., M. D., *San Francisco*

WE HOPE that Doctor Lyman's story of early medicine in California proves as pleasingly informative and interesting to other physicians as it has to the editors. The painstaking research and study necessary to bring this data together is apparent to any reader. The story is timely and a fitting introduction to this number of CALIFORNIA AND WESTERN MEDICINE, devoted largely to incidents in the history of medicine.

Doctor Lyman has prepared a complete bibliography for his article, and will be glad to lend it to any reader who may be interested.—THE EDITORS.

THE Medical History of California, owing to the three governments, which at different times have held sway over her, naturally falls into three divisions. History and medicine have progressed side by side, and it is difficult to give a survey of the latter without recording the events that moulded its development. On this account, California Medical History is here described under the following heads:

The Spanish Period, 1769-1822.

The Mexican Period, 1822-1848.

The American Period, 1848-

THE SPANISH PERIOD, 1769-1822

Baja, or Lower California, having been settled by the Spaniards in the sixteenth century; and missions, to proselyte and educate the Indians, having been founded first by the Jesuits and, after their expulsion in 1767, by the Franciscans; Galvez, the Royal Spanish Visitador-General, and Fray Junipero Serra, the president of the Franciscan establishments in California, decided, in 1769, to found a mission in Alta California at a place called Monterey, which Vizcaino, the Spanish navigator, had first visited and taken possession of in the name of the King of Spain in 1603. Accordingly, two expeditions, one by land headed by Portola and Fray Junipero Serra, and the other by sea, set out for Monterey, California. The sea forces were transported in two paqueboats, the San Antonio and the San Carlos. It is interesting to note here that the San Carlos, the flagship, also bore the name of the "Golden Fleece," interesting in that the Argonauts, California, and the Golden Fleece became synonymous just eighty years later.

So on January 9, 1769, Galvez, having delivered a stirring farewell oration to the future colonists, and the venerated Padre Junipero Serra having blessed the flags and administered the sacrament, the paqueboat San Carlos, the Mayflower of the Pacific, set sail from La Paz, Mexico, with Monterey as the goal, and San Diego the first rendezvous. There were sixty-two persons aboard that ship, including Commander Vicente Villa and his crew, a Franciscan Friar, Fernando Parron, Pedro Fages, a Lieutenant in the Royal Spanish Army, who later became Governor of California, Constanso, the diarist and engineer, twenty-five Catalan soldiers, a baker, two blacksmiths, a cook, a bleeder and the one who concerns us most, Pedro Prat, the surgeon. Bancroft says that he was a Frenchman, but he was a native of Barcelona, Spain, and a graduate in medicine from the University of Barcelona, where he was a surgeon of note. Holding the rank of Capitan in the Royal Spanish Army, he became the first Surgeon-General in the Royal Presidio of Monterey, and the first resident doctor in California. And so the medical history of California goes back to the cradle of the new Spanish province; the sword, the cross, and the scalpel proceeding hand in hand, and had it not been for the presence of Pedro Prat, it is probable that the projected province would have miscarried and never withstood the travail of its birth.

A few days after leaving La Paz, scurvy, then the scourge of the sea, broke out among the passengers. To add to this dilemma, through leaking casks their supply of water was exhausted, and to replenish they stopped at Cedros Island, where the spring was contaminated and the scurvy-ridden ship was ravaged by dysentery and death stalked in their midst. Later, the ship lost her way in the fog and sailed too far north. During the night of the 110th day from La Paz, she dropped anchor in San Diego Bay. The San Antonio, having sailed almost one month later than the San Carlos, was already there, and at dawn, April 29, the pilot spied the latter ship riding at anchor, but with her deck apparently as spectral as that of the "Ancient Mariner," as not a person was seen moving about. The crew of the San Antonio put off in boats and found that not a man aboard the San Carlos was able to lower one, and the crew, excepting one sailor and one cook, were dead, and many of the soldiers were in a desperate condition from dysentery and scurvy.

Dr. Prat, who had been battling with disease and death almost since his departure, with the help of

the San Antonio crew, constructed a tent-hospital, the first in California, and removed the sick and dying to the shore. But the scourge of the San Carlos was contracted by the crew of the San Antonio, and Dr. Prat, Fray Junipero Serra and two other Franciscan Padres attended, nursed and, buried the victims. Ninety soldiers, sailors, and mechanics succumbed. Only one-third of the original colony intended for Monterey survived. So tragic was this initial baptism of the California shores, that "Punta de los Muertos," or Dead Men's Point, near New Town (San Diego) derived its name from the burial of their scurvy and dysentery-stricken soldiers and sailors—all of which is reminiscent of the first winter of the Plymouth colony on the Massachusetts coast. And so it was Pedro Prat, the first surgeon in California, who nursed the remnants of the Pacific Pilgrims back to life and accompanied them to Monterey, where the second mission was founded and where he became Surgeon-General and resided at the Presidio Real, Monterey having become the capital of California. But he did not long survive. His mind had been so harassed by the harrowing experiences at San Diego that he became demented and was unable to assort and label the large supply of drugs he had brought with him. During the following year he died, and was buried in the Mission at Monterey.

Eventually there were four presidios in California—in the North, San Francisco and Monterey, and in the South, Santa Barbara and San Diego—and the twenty-one missions were divided among them; but because Monterey was the capital of the province, the Surgeon-General remained at the Royal Presidio there, and Monterey became the medical center of the province.

The following is a complete list of the Surgeon-Generals of the Spanish Army who were stationed at the Presidio of Monterey during the Spanish regime:

Pedro Prat, 1769-1771; Pedro Castran, 1773-1774; José Davila, 1774-1783; Pedro Carbajal, 1785-1787; Pablo Soler, 1791-1800; Juan de Dios Morelos, 1800-1802; Manuel Torres, 1802-1803; José Marie Benites, 1803-1807; Manuel Quixano, 1807-1824.

The only surgeon of this time connected with the Mission Dolores was José Davila, a Spaniard. Very little seems to be known of him except that he picked the site as a healthy one for the Mission. He was present with Palou, Lieutenant Moraga, etc., when the cornerstone, not only of the Mission, but of the civilization of San Francisco was laid. And there he buried his first wife, Josefa Carbajal in November, 1780. The doctor did not endear himself to Governor Neve, and as early as 1781 he favored granting the surgeon leave to quit the country, as being incompetent and captious, but in 1783 both men died and were buried in the Mission church.

In 1792, José Antonio Romeu, the fifth Spanish Governor of California, lay dying at Monterey, and history records that it was Dr. Pablo Soler who made the diagnosis and prognosticated a fatal issue. This Dr. Pablo Soler, a native of Barcelona, Spain, and a graduate of the university there, was the most

noted and probably the most skilful of the Spanish-Colonial Surgeons-General in the Californias. He arrived at Monterey as an officer in the Spanish Royal Navy about 1789, and for a while was very contented in this frontier capital, but at length he became weary of his seclusion from learned men of his class. In 1798 he wrote to the King of Spain, complaining of his sad and unhappy fate in being thus confined within the walls of a remote presidio surrounded by Gentiles and comparatively deprived of society, and begged to be relieved. At the same time he gave an account of his services to the California colony; his gratuitous attendance upon officers, missionaries, soldiers, pobladores or settlers and Indians, both Gentile and Christian, when called on; his traveling to remote ranchos, sometimes as far as forty leagues, to visit a sufferer and the difficult operations he had performed. In one case he had saved an Indian who had been gored by a bull so that his entrails protruded and dragged on the ground (and this in a time and region when anesthetics, sepsis, and sterilization were unknown). In numerous cases and during severe attacks he attended those afflicted with scurvy, chronic dysentery, and dropsy. The following entry from the old Spanish archives of the Mission San Carlos has this to say: "Dr. Don Pablo Soler is a great physician and a great surgeon. Had not his humanity prompted him to give his profession to the service of the California colony, he would have been renowned in Spain, but he gave the best years of his life for the welfare of the people, traveling many miles to minister to officers and soldiers, to settlers, rich and poor, to the missionaries, and to the Indians, to all with equal kindness. He was unable to cure Governor Romeu, but his consummate skill was none the less brilliant." About 1800 the King of Spain relieved Dr. Soler, and he was followed in quick succession by Dr. Juan de Dios Morelos, 1801-1802; Dr. Manuel Torres, 1802-1803; Dr. José Marie Benites, 1803-1807.

Although Robert Koch, the great German bacteriologist, did not discover the bacillus tuberculosis until 1882, Spain and Italy were the only countries in the earlier part of that century that believed that the great white plague was contagious and could be imparted one to another. That Dr. Juan Morelos shared this opinion cannot be doubted. In 1800 the Commandant, Hermenegildo Sal, died at Monterey of phthisis, and Bancroft is the authority for what follows: "His disease was in those days considered as contagious and, therefore, at the recommendation of the surgeon (Juan Morelos) all his clothing and bedding were burned, as was the roof of his house after the plastering had been removed from the walls." Again quoting from the same author, we find the following during the medical regime of Quixano: "On one occasion, while Governor Pablo Vicente de Sola ruled the Californias, a wealthy Spaniard died, leaving the whole of his property to the 'fondo piadoso de las Californias'; but, as he had been a consumptive, his furniture and clothing were burned, and in the excitement of the occasion his jewelry and money were lost or stolen. When the case was reported to the Viceroy of Mexico, the president of the College of San Fernando, who had

been made administrator of the estate, began suit against the authorities of the then Province of the Californias, from whom he claimed the full value of the property destroyed." These facts speak for themselves and for the Monterey surgeon in a day when neither the bacillus tuberculosis nor its etiological relationship were established.

In the year 1807 there came to Monterey Dr. Manuel Quixano, the last surgeon of the Royal Spanish Army, in which he also held the commission of Capitan. He was a native of Leon, Spain, and a graduate of the Royal Medical University of Madrid. Dr. Quixano first appears in history as a witness when, on August 10, 1809, in the hall of the Mission of San Carlos, Monterey, José Joaquín

consecrated Host were clasped to his breast. He was buried as found. Two years later, an old Indian neophyte of the Mission lay dying and requested the rites of the Church, and on his deathbed confessed that the good Padre, having been summoned in the dead of night to a dying Indian, had been treacherously murdered under a tree. Later the corpse had been placed in his own bed, and the door of his cell locked on the inside. Dr. Quixano being summoned from Monterey, the poor Padre's body was exhumed from his tomb in the chapel, and an autopsy was performed, disclosing that the Fray had been murdered in a most cruel manner, the details being so revolting that they were withheld from the general records.

Under date of 1815, we find the following entry in the San Carlos records: "Dr. Quixano made a tour of medical inspection of the missions, as serious illness afflicted especially the missionaries and Indians of Southern California. In every mission he was treated with respect due to his rank, but especially due to his ability and benevolence."

Up to this period the trend of California's civilization had been upward, and Monterey may be considered the cradle of this culture, but in 1822 the missions were secularized and in 1823 the rumble of revolution made itself heard. Mexico declared herself independent of Spain and claimed California as hers. A period of decadence was ushered in. Spain withdrew her troops from the Royal Presidios, and Dr. Quixano, with the rest of the Spaniards, retaining their allegiance to the Spanish Crown, resigned. On leaving his offices and those of his predecessors in the Monterey Presidio, the Spanish Government presented him as a souvenir the office chair which had been used at consultations by himself and his predecessors. This chair, the mahogany box which contained his fine medical instruments, and the scales in which he weighed drugs are now in the possession of his great-granddaughter, Maria Antonio Field of Monterey. After relinquishing his Spanish commission, Dr. Quixano retired to private practice among the settlers on the Monterey peninsula. He died in 1825, and his residence and office are now occupied by his descendants.

For seventy-five years and more following the foundation of the Presidio Real at Monterey, the three other presidios, the twenty other missions, and the numerous pueblos were absolutely without skilled medical attendance, and a sick or injured person was dependent upon the missionaries, the "hechiceros" or Indian medicine men, or the stranger within the gates. Occasionally, as we have seen, the surgeon was summoned from Monterey, or the medical officer from some visiting man-of-war or trading-ship was pressed into service. If the stranger within the gates happened to be an American or Englishman and the emergency required it, he was immediately summoned, as "an Anglo-Saxon in those days was synonymous with an M. D."

The Indian medicine men or "hechiceros," in spite of their weird performances, undoubtedly possessed considerable ability. Our pharmacopoeia has been enriched by three valuable vegetable additions discovered and used by the California Indians. *Eriodictyon Glutinatum*, which grows profusely on our

Chair used by Dr. Manuel Quixano and his predecessors in the medical offices of the old Royal Spanish Presidio of Monterey, now in the possession of his great-granddaughter, Miss Maria Antonia Field of Monterey.

de Arillaga, the eighth Spanish Governor of California, was required to take the oath of allegiance to Fernando VII, Charles IV having abdicated the Spanish throne. At 5 o'clock in the afternoon, the Governor entered the hall and, in the presence of the Friars, Surgeon Manuel Quixano, and the army representatives, knelt before the crucifix; placed one hand upon the Holy Evangelists, and, holding up with the other the cross of his sword, swore to bear true allegiance to King Fernando VII.

To Dr. Quixano belongs the honor of having performed the first recorded autopsy in California. On October 12, 1812, Padre Andres Quintana of the Santa Cruz Mission was found dead in his cell, with the door locked on the inside. He had been ailing for some time, and when found the Holy Oils and

foothills, was used by the medicine men in afflictions of the respiratory tract. So efficacious and so valuable did it prove to the missionaries, that they called it "yerba santa" or holy plant. The second, the *rhamnus purshiana*, which grows luxuriantly in the timbered mountains of Southern California, was used extensively as a cathartic. So highly esteemed was it by the followers of the Cross, that they christened it "cascara sagrada," or sacred bark. The third, *grindelia robusta*, was used in pulmonary troubles and as external skin applications following exposure from the *rhus toxicodendron*, or poison oak. That these "medicine men" possessed considerable knowledge of anatomy and drugs and their uses is beyond question. Bustamente, in his "History of Mexico," narrates an amusing incident of one of these medicine men or "hechiceros" who was called to the City of Mexico and summoned before the College of Physicians, on the charge of being a quack. In reply to the accusation, he asked his judges to smell a certain herb, which quickly produced a severe nose bleed, and then invited them to check it. Seeing that they were unable to do so, he administered a powder which immediately had the desired effect. "These are my attainments," he exclaimed, "and this is the manner in which I cure the ailments of my patients." So adroit was the fatal Borgia-like decoction which the Indians administered to Father Pujal at San Miguel, that Surgeon Morelos, although summoned there from Monterey, was unable, in spite of an autopsy, to ascertain its nature.

The Padres possessed considerable medical knowledge and were capable of doing minor surgery and even more complicated operations, and they were really the medical Gibaltars in their establishments. Bancroft speaks of one of the Fathers, Marcelino Marquinez of Santa Cruz, as being particularly adept in medical matters. Each mission had its hospital, a single ward supplied with mats instead of beds, and each Padre had his little medical and surgical kit, one of which is still preserved among the treasures in the Mission at San Juan Bautista. A case is on record of one of the Padres amputating the arm of a disabled Indian, and doing it so cleverly that years afterward its success was attested by one of the Friars of San Buenaventura (Bard).

It is interesting to note that the two first Caesarian sections performed in California were accomplished, though unsuccessfully, by Franciscan Friars, one in San Francisco in 1805, the other in San Jose in 1825. The missionaries were required to perform that operation on all women dying undelivered during labor. Perhaps it is not amiss here to add that the first successful Caesarian was performed by that surgical genius, Elias S. Cooper, in San Francisco in 1859, and is a monument, not only to Dr. Cooper's skill, but to man's ingratitude to man, as out of it grew one of the greatest medico-legal battles that ever engaged the California courts. Cooper's name and fame have endured, while the doctors who instigated the suit have been consigned to the oblivion they deserve.

Bleeding was very much in vogue during this period, and many of the soldiers whom the Spanish Government sent to California were enrolled as phlebotomists, their salaries averaging \$450 to \$800

per annum. The lack of capable physicians led to the bleeders being consulted on all manner of cases when the lancet was applied, whether the management of the case required it or not. The great Washington is said to have been the victim of an ill-timed lancet. Bleeding became so abused in this period of our medical history that the barbers added it to their repertoire, and finally became so proficient that Governor Diego de Borica, in 1799, issued a "bando" prohibiting them from exercising that art. It is amusing to note at this period of medical history that the barber and surgeon were very closely allied. The father of Handel, the English composer, was a surgeon-barber, and the military surgeon of the period was often required to shave the regimental officer. There is no historical evidence to prove that our worthy Spanish predecessors were sprung from this school. On the contrary, they were, in several instances, graduates of renowned Spanish medical institutions.

That the Surgeon-General at Monterey was often required to visit distant missions, ranchos, and pueblos is verified by the Spanish records. In 1804, during the time Benites was surgeon at Monterey, he was required by the Mexican Viceroy to visit a number of the missions on account of the alarming mortality. This he did and forwarded an able and exhaustive report of the diseases encountered and their treatment. In 1802 a number of the Padres at the Mission San Miguel sickened and died. They were said to have been poisoned by the Indians. Dr. Morales was hastened to the scene and made the investigation which followed.

THE MEXICAN PERIOD, 1822-1848

As we have seen in the previous chapter, the medical history of California during the Spanish regime was marked by a dearth of doctors, drugs, and diseases. During the fifty odd years consumed in this period, there never was more than one doctor at one time in the whole province. According to Humboldt's estimates, California's population in 1802 was 9000, another estimate in 1822 was about 16,000, and in 1831 some 23,000; so that it was well for the one doctor sponsoring this enormous population that there was a dearth also of disease. The Spanish doctor dealt principally with scurvy, chronic dysentery, and phthisis, although Lues was probably the captain of the men of death, as it was this disease that decimated the Indians; but the Mexican physician had to contend with a totally different category of ailments. With the coming of the "gringo," an array of "winged and wan diseases" followed in his train, chief among which was smallpox, which first manifested itself in 1798. In 1834 it was particularly virulent in Sonoma. Some 12,000 Indians are said to have died there during that outbreak, and so fatal was the type, that it was impossible to dig graves for the dead, and General Vallejo had them interred in trenches, often so shallow that the corpses were barely covered with earth, where they fell an easy prey to the hungry bears and wolves. Dr. Platon Vallejo, the General's surviving son, tells a tragic story of one of the supposedly dead smallpox victims of this epidemic being entombed alive in the trenches before death had claimed him. A hungry grizzly awoke him from his lethal

sleep, and his agonized cries brought help, but not until one leg was partially devoured by the bear.

In 1825 there was an epidemic of measles, and of scarlatina shortly afterward, and in 1834 cholera reared its frightful head.

Monterey continued the capital of the Mexican province, and the following surgeons comprised the medical staff, not only of the Presidio, but of the territory:

I. Evan Perez de Leon, 1829; Manuel de Alva, 1831-1840; Manuel Crespo, 1832; Edward Bale, 1840-1843; Fautino Moro, 1844.

Manuel de Alva was a Mexican surgeon who came to California with the Governor, Figueroa, who introduced printing into California. Although the doctor was somewhat of a politician, he was devoted to his Governor; but in 1835 Figueroa died of apoplexy and, having played a prominent part in the struggle for Mexican independence, he felt that the republic would wish to pay him fitting honors when dead. So, before succumbing, he requested that Dr. Alva would embalm his remains and have them entombed in the vaults of the Mission at Santa Barbara, there to await the honors which a grateful Mexico would bestow upon him in their capital city. This the doctor did, using a great quantity of arsenic. Ten years later they raised the lid of his casket, but nothing remained of the gubernatorial remains. Mexico never sent for the ashes, and Alva blamed the arsenic: "*Vanitas Vanitatis*." Two years after Figueroa's death, Dr. Alva, with other Mexicans, revolted against Alvarado, for which he was arrested and confined at San Miguel; but escaping, he joined the Carillo faction, only to be arrested again in 1838. He was released on a promise of non-interference in politics. At first he was noted as a freethinker, but at length, because of illness, became devout, and in 1840, obtaining a Mexican passport, he disappeared from the picture.

Manuel Crespo does not appear to have been an authorized surgeon, but a Mexican phlebotomist, and Fautino Moro played a small role for a brief period only as the Mexican "official de salud militar." In 1837, there landed at Monterey a young English surgeon, Edward Turner Bale, probably the first Anglo-Saxon resident physician at Monterey. He was a man of good education, but quarrelsome. Soon after his arrival, he married Maria Ignacia Soberanes, a niece of General Vallejo. The latter appointed him in 1840-1843 surgeon of the California forces, the only Anglo-Saxon who ever occupied that position. Soon after this appointment, he rented a room from the United States Consul, Larkin, with the idea of establishing a drug store. This degenerated into a liquor shop, and the doctor came into collision with the authorities. In 1841, he became a Mexican citizen, and his wife's uncle, General Vallejo, presented him with a large tract of land in the neighborhood of Yount's "Carne Humana Rancho," in the beautiful Napa Valley. There he went on the expiration of his appointment with the California forces. Not long after his arrival at the rancho, Capitan Salvador Vallejo paid his household a visit. Salvador had been long absent at the Indian wars, and his niece, Mrs. Bale, was delighted to see her uncle, and in true Califor-

nia fashion she expressed her pleasure most warmly and affectionately. But the doctor, being extremely jealous of his handsome wife, resented the affectionate greetings bestowed and exchanged, and challenged Capitan Vallejo to a duel. The latter was the most famous swordsman of his day in California, and far outclassed the doctor, whom he whipped as if he wielded a willow stick instead of a sword, which so incensed the doctor that he attempted to shoot his antagonist. This landed him in jail and almost cost him his life. A number of foreigners, notably the Kelseys, attempted to rescue him, which caused great excitement. In 1846, the doctor went into the lumber business, and he died a wealthy man in 1849.

In spite of the Surgeon-Generals being stationed at Monterey, there were many times in their absence from the capital when the settlers or sojourners were dependent upon the visiting medical men aboard men-of-war, whalers, or trading-ships, and it is a tradition in the Field family that they often pressed into service these visiting medicos. William Heath Davis, in his "Sixty Years in California," narrates an occasion of this sort. In 1831 he visited Monterey aboard the bark Louise. While she was lying at anchor in the bay, Davis fell into the main hatch, was rendered unconscious, and fractured his arm. At the time there was no resident surgeon in Monterey, and had it not been for the presence of that distinguished Scotch doctor, as well as botanist, who has left his name forever associated with our noble fir and spruce trees, Davis could not have recounted that delightful reminiscence of Dr. David Douglass, who came to these shores aboard the Dryad from the Columbia River country. Speaking of fractures of the arm and dearth of doctors, it is interesting to recall that the Portuguese navigator, Cabrillo, who first discovered these California shores in 1542, found a nameless grave on San Miguel Island in the Santa Barbara channel, because he had fractured his arm and there was no surgeon aboard to set it properly. It was a Russian physician, as well as naturalist, who came with the Russian exploring ship Rurik in 1816, Otto Von Kotzbuie, Commander, who left his identity indelibly and perennially emblazoned on the California hillsides. Dr. Johann F. Eschscholtz gave his name as the botanical cognomen of our famed poppy, which the Spaniards had earlier appropriately hailed as the "Copa de Oro."

Alfred Robinson, who came to Santa Barbara in 1829, records in his "Life in California" that there were no doctors in that country, and every foreigner was supposed to know something of the practice of medicine. One night, shortly after his arrival, being called upon to prescribe for a woman in great abdominal pain, he suggested a few drops of laudanum, which immediately relieved the sufferer, and established his fame as a medico. To illustrate the point further, he narrates the tale of an absconding American sailor who deserted his whaling ship at a neighboring port and walked to Santa Barbara, where he set himself up as a physician. His efforts were soon crowned with success among the ignorant class, where his pretended remedies wrought marvelous cures. But his medicines could not have withstood the acid tests of the pure food laws, to say

nothing of the prohibition agents, as his nostrums reeked of "aguardiente." Santa Barbara's first physician was probably not a sheep-skin M. D., but an old trapper, a native of Maine, endowed with all the lore of the woods, and the trail, and trained in the emergency school of the frontier. These hunters possessed considerable medical skill. Kit Carson, the hero of a thousand frontier romances, at the age of 18, and equipped with only a razor and a handsaw, successfully amputated, in an amphitheater of the woods, the shattered arm of one of his comrades and seared the blood vessels with a heated iron bar. Bard says "the stump would have reflected credit upon the modern aseptic surgeon." Pegleg Smith, the "El Cojo Smith" of Bancroft, having had his leg mangled by an Indian's bullet, and being alone in the wilderness, sat himself down under a tree, and with a courage born of determination and necessity, ligated his own shattered limb with a buckskin thong taken from his hunting-coat and then courageously amputated the useless member with his hunting-knife. Of this heroic school, Isaac Sparks was a disciple, and he practiced at Santa Barbara from 1833 to 1841.

In 1836, Nicholas Augustus Den arrived in Santa Barbara aboard the *Kent*. He came from an excellent Irish family, and was a brother of "Don Ricardo." Dr. Nicholas Den had studied medicine at the University of Dublin, although he was not a graduate (Bancroft). On arriving at Santa Barbara, he acquired considerable property and launched his career as a cattleman, which was the pursuit of pastoral California, and in which he amassed a fortune. But the settlers, knowing of his medical training, frequently called upon him and he was obliged to leave his rancho to relieve their ailments and sufferings. He was particularly adept as a phlebotomist. William Streeter was another pioneer medico of Santa Barbara. He had studied in several medical offices in New York, but had never acquired a diploma. He, with Stephan Smith of Peru, is said to have brought the first steam engine to California, which they set up at Bodega.

Probably the first regular M. D. to settle there was Dr. James L. Ord, assistant surgeon of Company F, Third United States Artillery. He arrived in 1847. The first time he did not remain long, but he returned later to spend the greater part of his life. Early in his career, he married one of the handsome daughters of the de la Guerra family. Thus, allied to one of the proud old Spanish-California families, he occupied a unique position in the early annals of California. For his surgery, he had a reputation up and down the California coast, and was frequently called to distant ports, notably to Monterey, to operate. Dr. Ord was a native of Maryland, and through his veins coursed, not only the blue blood of the old South, but the bluest of England, as his father was the romantic offspring of King George IV, and Mrs. Fitzherbert, whom he, as the Prince of Wales, had married in December, 1785. (Memoirs of James Ord.)

Another interesting figure of the 50's was Ramon de la Cuesta. Neither was he an M. D., but he served some time as an interne in a hospital and, although he had no desire to practice medicine, so

successful was he in the treatment of the diseases of children, that he was continually in demand in his neighborhood. He thus becomes the pioneer pediatrician in California.

Dr. James B. Shaw, a graduate of the University of Glasgow, and of the Royal College of Surgeons of London, was a pioneer of 1850, and he became the first president of the Santa Barbara County Medical Society, and one of the distinguished physicians of that community.

Although Los Angeles was founded in 1771, when it had a population of forty-four, it was not until January, 1836, with a population of some 1250 souls, that the first physician appeared, and he proved to be one of the most interesting figures that ever entered California, which Dr. John Marsh did by way of Santa Fe. He was a native of Massachusetts and a Harvard graduate, both in letters and medicine. According to the Archives of Los Angeles, under date of February 18, 1836, one Don Juan Marchet (John Marsh) presented himself before the Ayuntamiento or Town Council and declared his intention of locating there and also that he was a physician and surgeon. Permission to practice was granted February 25, 1836, in these words: "The Illustrious Body decided to give him permission to practice medicine, as he has submitted for inspection his diploma, which was found to be correct, and also for the reason that he would be very useful to the community." As his Harvard diplomas were written in Latin, no member of the Illustrious Body of the Ayuntamiento could read them. Neither could anyone else in the Los Angeles of the period designated, so it was necessary to take them to San Gabriel for the mission Padres to translate. There they were found correct, and the doctor was granted a license to practice. So he set up his office and must have had a considerable clientele, as there was no competition. Neither was there any money in the old pueblo, and he had to take his fees in horses, cattle, and hides. This seems to have bothered the doctor considerably, as Bancroft notes his parsimony, and as it was difficult to carry such currency around; so he decided to abandon the pursuits of Aesculapius and take to the pasture and range. This he did in 1837. The same year his name appears upon Larkin's books at Monterey, and shortly afterward he acquired Noriega's Rancho of "Los Madonnos," in the shadow of Mount Diablo near the modern town of Antioch. Here he became the pioneer physician of the district and accumulated great wealth in livestock. In 1844 Dr. Pickering, connected with Wilke's United States Exploring Expedition, and an old Harvard classmate of Marsh's, visited him at the rancho and found him living in a little hut, the life of a hermit. The doctor was instrumental in bringing the first immigrants to California. This party included Bidwell, who founded Chico and the State Normal School there. However, these first immigrants do not speak of Marsh in glowing terms. Neither does Bancroft eulogize this pioneer medico; but says he was peculiar, generally disagreeable, and was notorious for his parsimony. Yet he was honest, was possessed of more than ordinary ability, and several of the Californians, notably Vallejo, speak of him in terms of warmest praise. Like many of

the pioneers, he espoused a native by whom he had several children. He was murdered in 1856 by a party of young Californians in the neighborhood of Martinez. His rancho is still known as the Marsh grant.

That the barber-surgeon played some part in the early medical history of Los Angeles, is proved by an advertisement that appeared in Commercial street, and is quoted by Newmark: "Gentlemen will be waited on and have shaving, hair-dressing, and shampooing prepared in the most luxurious manner and in the finest style of the art, while cupping, bleeding, and teeth-extracting will also be attended to."

A most interesting figure in the Los Angeles medical world in the days "before the 'gringo' came" was Dr. Richard Somerset Den. The Angelinos, who held him not only with esteem, but with affection, dubbed him "Don Ricardo," and he fits most magnificently into our ideas of the "splendid idle 40's." He was an Irishman of culture and refinement and a medical graduate of the University of Dublin, where he received a thorough training as a physician, surgeon, and obstetrician. After his graduation in 1842, he was appointed surgeon of a passenger ship bound for Australia. On his return he visited his brother Nicholas in Santa Barbara, and resigned his position. He was then 22 years old. In 1843 he was called to Los Angeles to perform several difficult surgical operations. The outcome was so successful that the leading citizens, native and foreign, petitioned him to remain in Los Angeles, and this he did, starting practice there in July, 1844. From that time on until his death in 1895, he devoted himself to his profession there, with the exception of a brief period in 1848, which he spent at the mines, and about twelve years from 1854 to 1866, which he employed in stockraising at his ranch at San Marcos. He served during the Mexican War as chief physician and surgeon of the Mexican forces, and treated, among others, the famous American Consul, Larkin. Newmark says "he was seldom seen except on horseback, in which fashion he visited his patients, and was, all in all, somewhat a man of mystery. He rode a magnificent coal-black charger, and was himself always dressed in black. He wore, too, a black felt hat; and beneath the hat there clustered a mass of wavy hair as white as snow. In addition to all this, his standing collar was so high that he was compelled to hold his head erect; and as if to offset the immaculate linen, he tied around the collar a large black silk scarf. Thus attired and seated on his richly caparisoned horse, Dr. Den appeared always dignified, and even imposing." One of his associates, Dr. Walter Lindley, recalls him as "impressive" and that his magnificent black horse was always groomed to perfection. "Dr. Den himself was invariably well groomed, being at all times dressed as though he were going to a wedding. But he never attended his own, and died at an advanced age a bachelor. He never made a visit for less than \$20." His hobby was horse-racing, and his magnificent steeds were bred for him at Santa Barbara. As a miner in 1848, his luck was indifferent, but as a physician in the mining camps, his skill was so phenomenal that he is said to have received as much as \$1000 in a day for his advice and practice.

Dr. J. T. Griffin was another well-loved physician, not only among the pioneers, but among a later generation. He was chief surgeon of the First Dragoons and came with General Kearney overland to San Diego in 1846, and from there to Los Angeles in January, 1847, where he had charge of the General Hospital. But his medical history there really begins in 1854 and terminated August 23, 1898. He was a brother-in-law of General Albert Sidney Johnston of Civil War fame. He himself was a Virginian and a graduate of the University of Pennsylvania. Lindley says "he carried a brusque and somewhat forbidding mask to cover a tender, generous heart." His fame may be measured by the fact that he was summoned to San Francisco as a consultant on the renowned James King of William case.

Of quite another ilk was William Money, a Scotchman, who arrived in Los Angeles in 1844 "as the servant of a scientific man whose methods and ideas he adopted." (Bancroft.) He practiced for a long time after his arrival, and in 1855 issued the first medical book published in California, "The California Family Medical Instructor," which contained his three physical systems, fifty plates of the human body, and a list of five thousand patients who had been under his care, of whom only four died while under his treatment. It is said that not a copy of the book exists today which happened this way—"not that the book was fatal to the reader; it had very few, but the readers were fatal to the book." They could not throw it away fast enough. But Money was torn between his love of science and his passion for religion, and Cowan records in his bibliography his second book, entitled "Reform of the New Testament Church," by William Money, bishop, deacon, doctor, and defender of the faith of Jesus Christ. This self-constituted doctor and self-anointed bishop died in 1890 at San Gabriel, and left many tomes of California early medical history and his own scientific deductions, all of which were lost.

The first doctor in San Diego was Pedro Prat, who founded the tent-hospital at Dead Man's Point. From then (1769) until the medical officers attached to our army and navy detachments between the years 1844 and 1850, that community was at the mercy of the itinerant traveler of land and sea, the medicine man, the bleeder, and the chemist.

James Ohio Pattie, a Kentucky trader, played the role of one of San Diego's greatest medical benefactors. It was in the days (1828) of Echeandia, the Mexican Governor, that Pattie and his father arrived in San Diego. The former threw them both into jail, where the father promptly died, and James Ohio would have shared the same fate had it not been for his knowledge and possession of a medical fact and its means of accomplishment. Smallpox was raging in California. Already many thousands of the Indians and Spaniards had died, and Echeandia trembled in his gubernatorial mansion. In exchange for his freedom, Pattie, who possessed some vaccine, promised to vaccinate him and everyone else in the territory; so he was liberated and began his Herculean task at San Diego with the Governor, the missionaries, and then the garrison and neophytes. From there he worked northward, even-

tually reaching San Francisco and the Russian colony at Bodega. In all, Pattie claims (Personal Narrative) that he vaccinated 22,000 persons. For vaccinating the Bodega colony, the Russians gave him \$100. For his great service to the Territory of California, Padre Juan Cabot, probably in the name of the Governor, offered him 500 cattle and 500 mules with land on which to pasture the same, providing he would embrace Catholicism and become a Mexican citizen, both of which propositions he refused. But to him, undoubtedly, belongs the honor of having vaccinated at any one time more people than any other one man, doctor or otherwise, before or since in California history.

One of the earliest San Diego practitioners was Dr. George McKinstry Jr., a Virginian, who practiced there for over twenty years. Before he settled there, he had an adventurous career, being the first sheriff of the northern district at Sutter's Fort, and was a hero of the Donner party rescue, for whom, on account of his medical knowledge, he was able to apply relief measures, but he was never able to settle down to the general routine and grind of a practitioner. There were many days when he answered the call and disappeared for a long time among the Indians.

Other pioneers were Minder, Burr, C. Hoffman, and Robert H. Gregg. Dr. Wozen Craft, who had been a member of the first convention at Monterey, was also the first physician to locate in San Bernardino, and Dr. Cepbas L. Bard, the first graduate physician to locate at Ventura, although he had several worthy predecessors among the early pioneers who possessed some knowledge of medicine, but no degree thereof, notably Dr. Pali, a Castillian, Dr. Ishbell, and Don José Cruz, a man of ability who gave his services gratuitously.

In the North, although the Mission Dolores and the Presidio date from 1776, the medical history of the peninsula did not begin until the naming of the cove which extended between Clark's Point in the northwest to Rincon Point in the southeast—Yerba Buena. It derived this name from the plant, a species of micromeria which grew luxuriantly on the hillsides flanking the cove. Yerba Buena was a great favorite among the Indians, who had proved its medical worth as a febrifuge, emmenagogue, carminative and anthelmintic, and early Spaniards added it to their pharmacopoeia. Up to 1835, only vessels came to anchor in the cove, but during that year Captain W. A. Richardson was appointed the first harbor master and he built the first house the same year at Yerba Buena. Two years later Jacob P. Leese built the second house and the first store in the village. On the first of April, 1837, he married General Vallejo's sister, and the year following Rosalie Leese, the first child born in Yerba Buena, arrived on the scene. But there is no evidence that an M. D. presided at the momentous occasion, and it is probable that a partera or midwife, or a partero or man midwife, a functionary peculiar to the native Californians, did the honors. In 1836 Nathan Spear, a native of Boston, where he had been in the drug business, formed a partnership with Leese in the store which the latter had already founded. And although the village grew but slowly,

when any of the settlers for miles around were ill, Spear was pressed into service on account of his superior knowledge regarding drugs. In 1844 there were only half a dozen houses, and a population not exceeding fifty persons at Yerba Buena. In 1846 the population numbered 200; in 1847, there were seventy-nine buildings and a population of 459, and out of this number, according to the "Annals of San Francisco," three were doctors: Dr. John Townsend, Dr. Victor Fourgeaud, and Dr. E. P. Jones.

That Dr. John Marsh was in Yerba Buena in March, 1837, is proved by a letter in his handwriting from there, and still in existence (Kress), but the first resident graduate doctor was Dr. John Townsend. He was a Virginian by birth, and with his wife, and brother-in-law, Moses Schallenger, crossed the plains in 1844, being members of the Elisha Steven's party, which was the second to make the overland journey from Missouri and the first to cross the Sierras by way of the Truckee River, which subsequently became the railroad route. Townsend's ultimate idea in coming to California was to practice medicine, but as a side issue; he and Schallenger, when they left Missouri in May, 1844, carried a big consignment of silks and satins in their covered wagon which they intended to sell to the Spanish ladies on reaching California. But it was winter before the party reached the Sierras and the first snows were falling. This filled the pseudo-merchants with dismay, as they feared their supply of silks and satins would be water-soaked. Before they reached the summit, their horses and oxen were floundering in the snowdrifts, and it was evident to the doctor that his stock would be ruined long before he reached the Sacramento and Sutter's Fort, unless he could make some provision in the Sierras to house it until spring. So he and Schallenger constructed a log house and made it as water-tight as possible, and stored the precious satins away until the spring and summer suns would make their transportation possible. Schallenger remained behind to guard the goods while Dr. Townsend and his wife pushed on through the drifting snow to Sutter's Fort. Although Schallenger's experiences that winter, alone in the bleak fastness of the Sierras, do not concern us here, suffice it to say that the story of that winter is one of the great epics of the mountains.

On reaching California, Townsend embarked on an adventurous career, serving as Sutter's aid and surgeon in the Micheltorena campaign. In 1845 he was practicing medicine for a short period at Monterey, and in 1846 he built his residence, with office combined, on his fifty-vara lot on the south side of California street, between Montgomery and Sansome streets, where the Merchants' Exchange stood for many years. Here he hung out the first medical shingle posted in Yerba Buena, and here it may be said was rocked the cradle of medical San Francisco. Townsend took a prominent part in public affairs and, being a man of education himself, he was instrumental in founding the first school which was erected on the west side of the Plaza (Portsmouth Square) in April, 1848, and of which he, Dr. Victor J. Fourgeaud, C. L. Ross, J. R. Serrini, and William Heath Davis became trustees. He also laid out as a suburban town the Potrero Nuevo on the beau-

tiful sloping banks of Mission Bay, but owing to the distance from town, it was a long time before there was a demand for lots. In 1848 he was elected Alcalde, or Mayor, of the growing city, the name of which about this time was changed to San Francisco. It was also in this year that the doctor went to the mines, but finding that life not to his liking he returned to his practice in San Francisco. Later, in 1849, he bought a ranch near San Jose, and while he and his wife were enjoying their little holding, the cholera epidemic, which had first manifested it-

Scales used for weighing drugs, and the case for fine ear and nose instruments used by Dr. Manuel Quixano, now in the possession of his great-granddaughter, Miss Maria Antonia Field of Monterey.

self in the harbor, galloped down the beautiful Santa Clara Valley, and although the doctor did everything within his power to treat his neighbors and stay the wild havoc wrought in its track, both he and his wife fell victims to the scourge. And so ended the career of the first adventurous Aesculapian of San Francisco. Bancroft says he was a man of excellent character and of genial enthusiastic temperament. In the Clyman Diary, he is described as "much attached to his own opinions, as likewise to the climate and country of California. His pleasant wife does not enter into all her husband's chimerical speculations."

The second graduate physician and surgeon to arrive in San Francisco was Dr. Victor Jean Four-

geaud, who was born in Charleston, South Carolina, April 8, 1817, and was a graduate of the Charleston Medical College. After receiving his degree there, he supplemented his training by matriculating at the University of France, where he spent about four years doing post-graduate work, and was subsequently granted a degree. Being endowed with considerable literary ability, he commenced, while in France, a history of medicine. This subject engrossed him during the rest of his life, but I can find no record of its publication. On his return to this country, he settled in St. Louis, Missouri, which was then the pioneer land of enterprise. Here he started his professional career and his efforts were crowned with success and distinction, and he became there the leading medical man of the period. Among other achievements, he founded the St. Louis Medical and Surgical Journal and became its editor, but having acquired fame and distinction so early in his career, he began, like Alexander, to long for other fields to conquer. St. Louis, at this period in the early 40's, was the frontier station of the far West and the resort of the agents and employes of the great Astor "American Fur Company." The narrative of these trappers, traders, and factors inspired his romantic and adventurous disposition with the grandeur and resources of the Pacific side of the continent. At length he could no longer endure the humdrum existence of a frontier Missouri practitioner. He had climbed to the topmost rung of the St. Louis medical ladder of that day, and having reached the top and looking ahead he saw the years stretching away in an unendurable array, but beyond the horizon there was the Pacific, there was adventure! This fired his imagination; so he climbed down the ladder he had so painstakingly erected, rung by rung, and an April night in 1847 after a first day's march, found the doctor, his wife and their little son encamped alone twenty miles from St. Louis. Six months later, October 21, 1847, we find him again, encamping this time on the banks of the Sacramento River near Sutter's Fort at a point now known as the foot of J street (Sacramento). General Sutter, with the hospitality that always distinguished him, proffered the doctor the hospitality of his fort, but the latter preferred his nomad tent. Eleven days later we find him installed at Yerba Buena, on the Bay of San Francisco, predicting it would be the great metropolis of the Western coast. Here, and in Sacramento later, he made rapid strides to fame and fortune, in both cities occupying a foremost place in the medical world and becoming editor of the pioneer San Francisco Medical Journal. The gold discovery drew him to the mines, and in Sacramento he remained until 1863, when he returned to San Francisco, where he practiced until his death in January, 1875. He was universally mourned as honorable, noble and brave, and his laudatory obituary notices affirm that from "the responsibilities of his calling he never shrank, its exposures he never feared." According to Bancroft, his offices in San Francisco in 1847-1848 were in block 20, bounded by Kearny, Clay, and Sacramento. As we have seen, he was one of the founders of the first school in San Francisco, and he made the first assay of the gold found by Marshall at Sutter's Mill (Eldredge).

To stimulate immigration, which had lagged on account of the Mexican War, he was engaged late in 1847 to write a long article on California and the advantages it offered in its climate and soil to the husbandman, stock-raiser and artisan. This he did, entitling the same "The Prospects of California," setting forth its prospects and resources. This was printed in six columns of an extra number of the California Star bearing the date of April 1, 1848. The same date a courier was dispatched with two thousand copies overland on a contract to reach Missouri in sixty days and spread the document (Hittell). The paper of April 1 mentioned the rumored gold discovery and treated it as of no importance, but on June 14 the same California Star was compelled to suspend, as all its employes, even down to the printer's devil, had struck work and gone off to the diggings, and with this throng headed toward the auriferous hills went Fourgeaud and Townsend.

Although the Annals specifically mention three doctors as residents of San Francisco in June, 1847, exclusive of those connected with Stevenson's Regiment of New York Volunteers stationed here at the time (one of whom William C. Parker practiced in San Francisco up to 1876), I have had great difficulty in distinguishing the third medico and have finally discovered him in the person of Dr. Elbert P. Jones, the editor of the California Star, the first newspaper published in San Francisco. Dr. Jones, if his title denotes medicine, was a capable jack of all trades. The educated man of this generation was not a specialist in one line of endeavor. He could do many things well; for instance, Thomas Jefferson is said to have been the master of eight professions. Bancroft says he was a man of much talent and versatility. A native of Kentucky, he practiced law in San Francisco, was the first editor of the Star, kept the Portsmouth House, was a member and secretary of the Town Council, took an active part in political wrangles and became the owner of many city lots, and gave his name to Jones street. The doctor was a most eccentric character. He wore a long velvet-lined voluminous cloak with the air of a Spanish grandee, and it was said he had acquired more nuggets and gold-dust than any other man in California. And this gold became the grand passion of his life, and one of his greatest pleasures was to spread sheets upon the floor of his bedroom and to pour his gold-dust upon them. Then pushing his naked feet through the dust, he would take it up in great handfuls and shower it upon his head and shoulders and then roll and wallow in the glittering metal, thus partaking of the enamored Danae and her illustrious paramour, Jupiter. Dr. Jones was also a disciple of Bacchus, and once when under the influence disposed of some seventy-one of his choice lots. He died in Charleston in 1851. So ends the Mexican period, an era ushered in by revolution, and out by war. In a few communities were doctors with the traditions of a medical training behind them, but most of the pueblos and villages were dependent upon men who had a smattering of medical knowledge and who were glad to do what they could to alleviate the ills of their fellow-men gratuitously. As Bard expresses it, "everyone was a self-constituted physician and the provincial adage:

'De medico, poeta y loco,
Todos tenemos un poco.'

(Of medicine, poetry and insanity, we all possess a little) was the outcome of the times." The medical men of both the Spanish and Mexican periods occupy an unique position in medical history. On account of the lack of roads and the distances to travel in this sparsely populated country, they were dependent upon the broncho and so became expert horsemen. In the Mexican period the majority of the doctors were Anglo-Saxons, and brought in contact with another race they all became expert in the Spanish tongue. Peril and adventure dogged their footsteps. Many of them died violent deaths, and hardly a doctor mentioned here but would fill the role of a hero in one of our modern novels of romance and adventure, but their labors and privations were fully appreciated, and no one stood higher in the esteem of their respective communities than did these pioneer physicians.

THE AMERICAN PERIOD, 1848-

Not only did the Treaty of Guadalupe Hidalgo terminate California's Mexican connection, but it also severed the government medical tie, and the last Surgeon-General of Spanish extraction returned to his home. During both of the preceding periods, Monterey had been the medical center of California as the seat of the Surgeon-General; especially was this true during the Spanish regime, when California could boast but one competent medical advisor at a time, but during the Mexican period, due to the increase in population, such important communities as San Diego, Los Angeles, Santa Barbara, Santa Cruz, and San Francisco began to attract their own medical advisors, as related in the preceding chapter. At the close of the Mexican War, San Francisco, which was just emerging from the village of Yerba Buena, became the maritime rival of Monterey and could boast of three doctors, but Marshall's discovery of gold during the winter of 1848, in the tail race of Sutter's Mill at Coloma, turned the trend of California's development, and she awoke from her pastoral dream to find herself at the vortex of the mining furore. Immediately the whole coast from San Francisco to Los Angeles, from the seashore to the Sierras, "resounded with the sordid cry of gold," and California emptied her male population into the "Diggings." Even the doctors—Bale of Monterey, Richard Den of Los Angeles, McKinstry of San Diego, Townsend and Fourgeaud of San Francisco, flocked to the mines, but not as physicians. They had exchanged the scalpel for the shovel. Not only was California resounding with the cry of gold, but the whole world had heard that report even as it had responded to the momentous shot of Bunker Hill. Bishop Berkeley's prophetic words became fact. If, as it had been said, "every road leads to London," in "the days of '49" the proverb was reversed and every road by land and sea was choked by the Argonauts headed toward California. The San Francisco Bay became a leafless forest, so close were the masts of the deserted sailing vessels packed together. And among these immigrants and emigrants estimated at 100,000 up to January 1, 1850, were hundreds of doctors, all bent on one thing—mining. So to understand just what type of medico swarmed about California's auriferous ravines like bees about a hive, it is necessary to conduct you to the gold mines which clus-

tered about Sacramento, the medical center of the Golden Age. "Dame Shirley," the wife of Dr. Fayette Clappe, a Massachusetts physician and surgeon who came to these shores in 1849 and opened the first medical office at Rich Bar on the Feather River, supplies us with the best medical picture of those stirring days in the mining camps. At first Dr. Clappe was the only doctor on the Bar, but in a few weeks he was one of twenty-nine, although the population did not exceed one thousand. His office was the only one on the river, and was a "beautiful architectural idea embodied in pine shingles and cotton cloth." It was ten feet long; a bench like a divan ran the whole length of the room. A rude nondescript in one corner, on which was ranged the medical library consisting of half a dozen volumes, did duty as a table. Shelves, which looked like sticks snatched hastily from the woodpile and nailed up without the least alteration, contained quite a respectable array of medicines. The white canvas window stared everybody in the face, with the interesting information painted on it in perfect grenadiers of capitals that this was "Dr. —'s office." The walls were decorated with sundry pictures from Godley's, Graham's and Sartain's magazines, among which fashion-plates with imaginary monsters sporting miraculous waists predominated. One day Dame Shirley visited her husband's office and encountered there a patient, a young Georgian who had not had the opportunity to speak to a woman for two years. So elated was he over the event, that he rushed out and invested in a bottle of champagne which Mrs. Clappe assisted the office force in drinking, acting on Willie's principle of "doing in Turkey as the Turkeys do." This bit of atmosphere is repeated, as nothing could be done in the California of that day "without the sanctifying influence of the spirit," even if it was in a doctor's office.

All the gold seekers were heirs to frightful accidents. The doctors dealt not so much with disease, although typhoid, malaria, erysipelas, and dysentery ran rampant in the mountains, as they did with surgical cases often of a terrible nature. What the mountain mining camps really required was a force of our modern ambulances and emergency surgeons. Great rocks were frequently rolling down the steep mountains and maiming the unsuspecting miner working in the river bottoms, or the unwary fell into the numerous pits of the prospectors which honey-combed the canyons. Dame Shirley records that "in the short space of twenty-four days we have had several murders, fearful accidents, bloody deaths, whippings, a hanging, an attempt at suicide, and a fatal duel." The accidents included stab and gun-shot wounds, shattered limbs and thighs, and compound fractures. This type of case taxed the ingenuity of the surgeon to the utmost and he was forced to act quickly and undertake the gravest surgical operations without counsel or time to prepare himself for the duty. Dr. E. S. Cooper, who founded the first medical college in California in 1859, in realizing the emergency equation in California surgical work, offered in the first prospectus of the Medical Department of the Pacific, a course in experimental surgery by vivisection—the class to repeat these experiments under the eye of the Pro-

fessor of Surgery, to school the hand, the nerve and the eye of the pupil in order to prepare himself for the numerous casualties and emergency cases encountered. The first surgical case upon which Dr. Clappe operated at Rich Bar was that of a Massachusetts lad, whose leg had been mangled by falling rock. The poor fellow was horrified at the idea of an amputation in the mountains and lay helpless for about six months in his bed, nursed only by the red-shirted miners. First typhoid assailed him, then erysipelas attacked the shattered limb and reduced it to a mass of disease. His intense sufferings were beyond description. Dr. Clappe felt that nothing but an amputation would save him. The other twenty-eight doctors on the Bar opposed him en masse, arguing that the patient would expire under the knife and it was cruel to subject him to further suffering, but they all agreed he would succumb unless the diseased leg were amputated. So Dr. Clappe decided to operate. Failure meant the loss of his reputation, but he waived all selfish considerations and the result was triumphant; although the patient's existence and Dr. Clappe's reputation hung in the balance for many days. Its successful outcome was no mean accomplishment in a day distinguished for its lack of every surgical appurtenance.

The life of another pioneer medical man in the Diggings, Dr. Edward Willis, is related by John Harwood and illustrates two types of doctors who flocked to the mines. Willis was an English surgeon, a graduate of Edinburgh and London, who settled at Placerville, in the days when that community consisted of "two chapels, six taverns, five stores for groceries and dry goods, a gambling-house and a printing office." All the rest of the dwellings were huts or tents, mostly tents. The doctor established himself under canvas, dividing his tent into two unequal parts with a piece of sail-cloth. The larger of these compartments he used as a dwelling, the smaller he styled grandiloquently the "Surgery," and there he spread out on rough pine shelves and an unplanned table his store of medicaments, surgical instruments and general scientific apparatus, some splints, a great jar of leeches, a microscope, a stethoscope, the implements of dentistry, a few chemical retorts and alembics, and several bottles containing preparations preserved in spirits which the doctor had purchased in San Francisco, and were intended purely for show, as the miners stood in great awe of such matters, and considered no doctor worth his salt who had not something curious wherewith to astonish them. At the entrance to this canvas abode, the doctor erected a blue sign inscribed in gold letters, "Surgery," and below, "Dr. Edward Willis, M. R. C. S., Surgery and Physic in all branches. Sets bones, draws teeth painlessly, bleeds, advice gratis." The surgery became a favorite rendezvous for the miners in tattered jerseys and picturesque black beards, and although they sought but little medical advice, they kept the atmosphere of the place blue with smoke and the earthen floor lubricated with tobacco juice. At the time the Englishman arrived there was one other doctor in Placerville. He was an American—Hullings by name and was said to be a man of learning and ability although a debauchee, but it is doubtful whether he ever saw a

regular medical college or possessed a sheepskin. He was tall and bulky, wore a black coat, a Mexican sash round his waist and velvet calzoneros of a bright green. He was generally too drunk to feel a pulse, much less to perform an operation, although the greater part of a practice at the Diggings was of an emergency type and at that surgical. Hullings resented the new doctor's arrival at Placerville, as he considered that location, by preemption, belonged to him. Dr. Cooper speaks of this same spirit manifesting itself in San Francisco at the time of his arrival in 1855. Those who came earlier felt that a previous advent and earlier residence amounted almost to superior caste and precedence, and greeted the new professional men with positive enmity and distrust. Hullings instilled this same feeling in Dr. Willis, finally announcing that the Englishman would have to leave. This he refused to do and the former arrived one day at his "surgery" and requested a sight of the Englishman's diplomas and certificates. Called on thus publicly to show his diplomas, Willis could not refuse, and Hullings had no more than received them than he tore them across the middle and then deluged their owner's face with a jet of tobacco juice. In the duel which followed, Hullings paid this insult with his life, and if they had death certificates in those days it bore the triumphant name of Edward Willis, M. R. C. S., and that was how he obtained his California practice.

James L. Tyson was another doctor of the '49 period who arrived in San Francisco, then a town of "wood and muslin," in May of the pioneer year and proceeded to the "Diggings" where he proposed practicing. He shipped for Sacramento on a sailing vessel. His passage cost him \$25, exclusive of food or stateroom, the passengers being forced to provide their own meals, and for bunks to wrap themselves in their blankets on the deck. Having arrived at Sacramento, it cost him another twenty-three-odd dollars to transport his baggage by oxen to the Dry Diggings on the south fork of the American River. There he set up his office in a tent and indulged in considerable bleeding. Although perfectly well, the miners would insist on its performance, and as the charge was an ounce of gold for each, he would gratify them and sometimes would have two or three bleedings around his tent at once. As the food supply at the mines was limited, the miners were forced to a diet of dried and salted meat. Vegetables and fruit were almost unknown. As a result, scurvy was one of the chief complaints of the mountains and was the underlying cause of most of the existing diseases, consisting of rheumatism, dysentery; and brain fever, intermittent, remittent, and continued fevers, the latter early assuming a typhoid character. As most of the gold-seekers continued to work while ill, Tyson records in his "Diary of a Physician" that he never saw so many broken-down constitutions as during his brief stay in California. He enjoyed a considerable practice at the "Dry Diggings," but was finally induced to build a hospital between the Yuba and Bear rivers on a spur of the Sierras, and there he went with his building material strapped to his saddle, which consisted of 100 yards of cotton duck which he made a special trip to the "Embarcadero" at Sacramento to procure. With the help of his cook and steward, some tall, slender pines

were felled, upon which the duck was stretched, and so the hospital was constructed, but before it was completed a poor fellow lying under the trees begged for admittance. He had been on a prospecting tour, seeking a suitable place in the deep canyon and ravines to dig, when suddenly seized with vertigo and sickness, and was now suffering from "bilious-typhoid." In the evening two others came from a neighboring canyon, suffering from dysentery, and the day following twelve Oregonians bore one of their number six miles on a litter to the hospital. These with several other cases soon filled the tent hospital and kept Tyson busy until the snows drove him back to San Francisco, where he notes: "All who had any tendency to diseases of the chest suffered during their stay in the bay city."

J. Tyrwhitt Brooks was likewise a pioneer doctor of the Bear River country. An Englishman, he came to California during the Mexican War to engage in surgery, hoping to attach himself to the Army of the U. S. A. The gold excitement drew him to the mountains, where he engaged in mining and doctoring, receiving an ounce of gold for every patient seen. Between his shovel and scalpel, he amassed considerable gold-dust and nuggets. The amount becoming so prodigious, he was fearful of carrying it about with him and finally entrusted it to a faithful courier bound for Monterey, where it could be banked. En route the courier was attacked by a famous robber of the mines, who lassoed him while riding and dragged him from the saddle, and while he lay wounded and unconscious, escaped with the doctor's hard-earned wealth—all of which is told most graphically and dramatically in "Four Months Among the Gold-Finders in California."

Sacramento was the center of all this mining activity and a great many of our pioneer doctors first hung out their shingles in that city, although they later drifted to other California points. In May, 1850, there were fifty doctors there; probably more, but that number signed the roster of the Medico-Chirurgical Association, the second medical fraternity founded in the state. Stillman felt it was the first association of its kind in the "Republic," but the one founded in Los Angeles in January of that year antedates it by four months, but I will have more to say of these first medical associations under another heading. Suffice it to say now that three of the medical officers of that pioneer society had been presidents of county societies at home. The vice-president of the same, Dr. John F. Morse, founded there in 1856 the first medical journal published in California. It is also worthy of note that one of the first hospitals in the state was built in Sacramento in 1850, and also the State Medical Society was founded there in 1856. More of these anon, but this will prove the pre-eminence of Sacramento during the Golden Age as the medical center of California.

Dr. J. W. Palmer, who was city physician in 1849, in his book, "The New and the Old," gives the best medical picture of San Francisco of this period. Most of the physicians had their offices in tents. Of drugs, quinine was the panacea for all the ills to which California flesh was heir. Palmer sold his supply at auction for \$64 an ounce. As for rents, \$100 per month for a "dog house" was not exces-

sive. When he landed, the doctor was so poor that he slept on a free sand-hill, where the fleas were so fierce that his health was undermined; but finally he got under way through a lucky "monte game," which enabled him to set up an office where he was soon making \$75 to \$100 a day. Medical fees were enormous—two ounces of gold-dust (\$32) a visit; but this was not excessive in a day when laudanum cost \$1 a drop, quinine \$1 a grain, when boots cost \$40 and blankets \$100 a pair, potatoes \$1 a pound, and \$5 for a haircut.

"Gold! Gold! Gold! Gold!
Bright and yellow, hard and cold,
To the very verge of the churchyard mould
Good or bad a thousandfold."

Of the type of medical man that came to California during this period much may be written. "Time's effacing finger" has erased the records of hundreds, but a few are still traceable in the footprints they left behind them. The majority were the pick of the land, well educated, industrious and respectable. San Francisco is yet reaping a rich medical heritage in the bequests of three of the surgical giants of this period. True, these early physicians and surgeons were carried away by the mining excitement, but it would be difficult to find a red-blooded man of this era who had not succumbed to the prodromes of the gold fever. The majority of these medicos in their own communities had been men of professional skill and renown who had left practices of magnitude and homes of ease and comfort to seek new ones here. With Hemans we might ask: "What sought they thus afar?" Why did they exchange the known for the unknown? Gold alone was not the quest of this exodus. Most of these were amassing that at home. Toland had a \$16,000 a year practice long before he exchanged the comforts of Columbia, South Carolina, for the perils of the plains. Henry Gibbon Sr. was a professor in the Philadelphia Medical College with a large clientele behind him years before he crossed the Isthmus. Elias S. Cooper had already climbed the ladder of success, founded the State Medical Society of Illinois, given medical instruction and acquired a reputation as a daring and skilful surgeon, especially in deformities of the extremities and defects of the eye, as well as a competency before he left Peoria in his background. H. M. Gray, Stephen R. Harris, and J. C. Tucker were occupying professional places of assurance and eminence in New York when the star of California first appeared above their horizon. What was it, then, that made them stop, look and listen like the wise men before them? It was adventure, and California was the greatest one of the nineteenth century. Of these pioneer doctors who risked the dangers of the ocean and the perils from savage and famine on the plains, it may be said, with the historian, that only the brave attempted it and only the strong survived, qualities that marked them in some degree as superior to their fellows. Having endured these dangers, it was only the persevering, energetic and shrewd who were able to succeed, and eventually to found the cornerstone of medical education on the Pacific Coast. What they earned from the world by genius and untiring energy, they gave back a thousand-fold in ideals and gifts to humanity. Our great hospitals and medical colleges of the Uni-

versities of Stanford and California, our medical societies, medical magazines, endowed beds, and the Lane lecture courses and medical library are all monuments to these men of heroic mould. Of this timber were Elias S. Cooper, who builded better than he knew. He was the prime originator and ardent promoter of medical education on the Pacific Coast, a graduate of the St. Louis (Missouri) Medical College. During the 50's he had the courage, daring, training and skill to resect parts of three ribs and to remove a foreign body (the breech-pin of a gun) from beneath the heart of one of his patients, to ligate the abdominal aorta, in another the primitive carotid, to open joints, to perform a successful Caesarian, to remove a large fibro-cartilaginous tumor from the uterus; to found the first medical college west of the Rockies; and to organize the California state and county medical societies; another was Hugh Huger Toland, who left a munificent practice at Columbia, South Carolina, to cross the plains, traversing the distance between Independence, Missouri, and San Francisco in seventy-six days, the shortest on record. He lived to found a great medical school—that of the University of California—to endow and bequeath it to the state, to amass a fortune which ran into the millions, to occupy a place in his medical world which few have attained since or before, and to be a benefactor to all the worth-while medical institutions of his time and state. Of such timber were J. D. B. Stillman of New York, who was a founder of the early medical institutions of Sacramento, including the first hospital and medical association, and who has left a rich medical heritage of this epoch in his book, "Seeking the Golden Fleece," and Henry Gibbons Sr., a native of Wilmington, Delaware, where his father was a prominent physician. Both father and son were graduates of the University of Pennsylvania, having received their respective degrees some twenty-seven years apart. At the outbreak of the California gold excitement he was one of the prominent physicians of Philadelphia, but he gave it all up to follow the star of Empire. When he arrived in San Francisco in August, 1850, cholera was raging and he was put in charge of the cholera hospital. From that time on until his death, he was connected with everything worth while medically, and was foremost in every measure and organization tending to the education, welfare, and improvement of the people. To him belongs the honor of having given the first course of medical lectures in California. Now they would correspond to the endowed Lane Medical lectures. He inaugurated this course during the winter of 1850-51. One was given every week for thirteen consecutive weeks. That he was not a member of the first medical society founded in San Francisco, was due to the fact that that organization antedated his arrival by two months; but of its reorganization in 1853, as we shall find, he was the first president; likewise, of the County Medical Society founded in 1856, and of the State Society founded the same year, he became the second president. Of the medical department of the University of the Pacific, he was a co-founder and member of the faculty. When that institution crumbled, he became an initial member of the faculty of the Toland

Medical College, now the Medical Department of the University of California. With the resuscitation of the Pacific Medical College, the ancestor of Cooper Medical, Dr. Gibbons became one of the pillars of this institution. His son, Henry Gibbons Jr., who had received his "Toga Virilis of medical manhood," as Dr. Lane was wont to say, from the Medical Department of the University of the Pacific, devoted a lifetime of medical usefulness as dean to all the forebears of the present Stanford University Medical School.

R. Beverley Cole, graduated at Philadelphia, arriving in San Francisco in 1852 aboard the Cherokee, was one of the most picturesque of the early prominent physicians. At the time of the historic murder of James King of William in 1856, Cole was Surgeon-General on the staff of the Grand Marshal of the Vigilance Committee and, with Dr. Nuttall, one of the two first physicians to reach the wounded man. Subsequently, Drs. Hammond, C. Bertody, H. H. Toland, and H. M. Gray had charge of the case, and Cole withdrew chagrined. As time progressed, the condition of the patient became more and more desperate, and in spite of everything his physicians and a legion of the "faculty," including Dr. J. T. Griffin, U. S. A., who was summoned post-haste from Los Angeles, could do, James King of William died, and the Vigilance Committee, which had been called into being by this crime, strung up James P. Casey, the assassin. (See R. K. Nuttall, San Francisco Chronicle, June 4, 1856.) In February, 1857, the State Medical Society convened at Sacramento, and Beverley Cole sprang his bombshell by affirming that Mr. King's injury was a flesh wound and "not at all dangerous, and that with ordinary care and judgment there would not have been the slightest danger to the life of the wounded man" (Alta California, March 5, 1857), further stating that "a sponge was left in the wound five days which he did not hesitate to denounce as a case of gross malpractice." It is hardly necessary to state that these words created an uproar among the medical gentlemen present, included being the late Mr. King's four doctors. Out of this murder grew the Edward McGowan trial at Napa, and Beverley Cole and H. H. Toland were arraigned as witnesses on opposing sides. The testimony of both was very bitter (Alta and Bulletin, June 1, 1857), and a great war among them and their professional supporters ensued. But in spite of all that occurred then, it is interesting to note that R. Beverley Cole became, when it was founded, Dean of the Toland Medical College and subsequently of the Medical Department of the University of California. The following jingle apropos of Cole's remarks on James King of William's death, appeared in the daily press of the time:

WHO KILLED COCK ROBIN?

Who killed Cock Robin?
I, says Dr. "Scammon"
With my chloroform and gammon
I killed Cock Robin.

Why was it given
In a smothering dose, by heaven?
I refuse to say
Replied Dr. Gray.

Who put in the sponge?
I, says Dr. "Lunge,"
They did me impunge
So, "bedad," I left in my sponge.

Who found the sponge in the body?
I, says (clever) little Bertody,
I found it in the body.

Who took it out?
I, says plucky Stout,
I took it out.

Who blabbed the whole
I, says Dr. Cole,
It lay on my soul
And I blabbed the whole (Medicus).

When Dr. Cooper founded the Medical Department of the University of the Pacific, he appointed Beverly Cole Professor of Obstetrics and Diseases of Women and Children (note pediatricians, the first in San Francisco), as well as dean of that institution. The State Medical Society convened in February, 1859, and Dr. Cole read a report on "Obstetrics and Diseases of Women in California," and, although the speech was delivered in the days before the radio, it was broadcast all over the United States and reverberated on California's shores; so great was the "tempest in the teapot" caused by his unguarded words. In this paper, he said in part, speaking of the pioneer women of California, removed at the most critical period of their lives from the healthful advice of their mothers, that three out of four of those ladies, both married and single, "who have reached the age of 15" are no better than they should be, and he compared them to a certain woman of Babylon as being the "victims of this dissipation and fashionable life, yielding to the solicitations of the opposite sex and finding themselves in a short time the prey to disease." (Bulletin, January 6, 1859.) Although his report was read before the medical society of the state, when "at least one hundred of the most prominent medical men were present," and was intended for scientific and medical minds only, one of the Albany (New York) papers took it up with reflections upon the morality and chastity of the women of California. Immediately all the California publications flew to the rescue and engaged in a wild denunciation of Cole. Although the doctors present at the original meeting when the paper was delivered heard nothing amiss and then made no comment, they now commenced to vilify Cole as the "Woman Traducer." Even the laity of his city and state were up in arms against him. His practice was in jeopardy, and he was persecuted far and near. Finally the medical society itself took up the cudgels and he was exonerated of any "evil intent to defame the character of the women in the state, although there can be no doubt that the language of the report in question was very loose and improper" (Bulletin, February 14, 1859), the vote of exoneration standing, "ayes" 22; "noes" 8. The feeling must have been very intense, as we note as a result of the vote such prominent physicians as these resigning: A. B. Stout, J. P. Whitney, C. Bertody, T. M. Logan, S. R. Gerry, V. F. Fourceaud, H. M. Gray, and Sharkey. And so it would appear that these pioneer medical giants who had no fear of the terrors of land or sea were likewise not afraid of one another. Cases are on

record where their tongues being inadequate, they resorted to arms.

Another important medical figure of the 1849 period was Isaac Rowell, a graduate in arts, science and medicine of Dartmouth College. At the time of the gold discovery, he was practicing in Maine. He arrived in San Francisco via the Cape in June of the pioneer year, and started his practice in which he was immediately and ultimately successful. He was one of the staunch preservers of the Commonwealth in those exciting days before the Civil War conflict. For a number of years preceding her admission into the Union as a free or slave state, California's fate hung in the balance, and probably no man of his time in California did more for Lincoln and the rights of man than Dr. Rowell. He gave up his practice temporarily and stumped the state, and this in the pre-train days. He also organized and commanded "the first California Mounted Battalion." Of the original faculty of the Medical Department of the Pacific, Rowell occupied with distinction the chair of chemistry, and for a time that of surgery, too. He was also a supervisor and health officer.

Another prominent medico of these days was Stephen R. Harris, the third Mayor of San Francisco. A graduate of the College of Physicians and Surgeons, Columbia University, New York, and for six consecutive years a New York health commissioner, he came to San Francisco in 1849 via Panama. In those days that disease-infested country, the half-way house to California was congested with crowds seeking cabin room to San Francisco. At one time six thousand were detained there several months and among them Dr. Harris. A frightful dysentery epidemic broke out and there hundreds found their graves. The doctor devoted his time and services to the stricken Argonauts and raised funds from the Masonic and Odd Fellow lodges to alleviate their wants and give the dead a decent burial. At length he reached San Francisco in June, 1849, and founded the first real drug store at the corner of Clay and Montgomery streets. He stocked it with a \$20,000 supply of medical goods, the most extensive establishment in the country. Just as fortune's smile seemed most propitious, along came the great conflagrations of May 4 and June 22, 1850; May 4 and September 17, 1851, to again test the mettle of his soul. He lost all he possessed, having replenished his supplies after each successive fire. In 1851 he became Mayor, but continued to carry on his practice.

Dr. Robert McMillan, a native of South Carolina, a graduate in arts and medicine of the University of Pennsylvania, and a Paris post-graduate, entered the Golden Gate early in 1849, one of the best trained medical men, as well as a ripe scholar, and one of the most profound students that ever sought these shores. It was from his office that H. H. Toland launched his brilliant career.

Another medical man of the '49 period who distinguished himself in his day and generation, both in New York and California, was Henry M. Gray, a graduate of the Geneva Medical College, who came to these shores in December, 1849, aboard the *Hope*, a bark owned and manned by Gray and ten of his

college mates and associates. Having arrived in San Francisco the doctor visited the mines, only to find that his place in life was among the sick, distressed, and maimed. So he returned to San Francisco, commenced practicing, and devoted his great powers, tender sympathies, and cheerful presence to alleviating suffering and illness. Although possessed of the most considerable clientele in the city, he distinguished himself by the amount of his gratuitous practice, being always ready to assuage the suffering of the poor and wretched. On board ship he found his way to the steerage to attend the helpless and afflicted. On his visit to the Yosemite in 1861, he went far out of his route to prescribe for a wounded hunter dying in his cabin among the lonely Sierras. His helping hands stretched beyond the grave. Even when he lay in the shadow of death, he gave a list of the worthy poor who had long received gratuitous practice at his hands to a professional friend and charged him with their care. In other words he raised charity to a cardinal virtue. He was an eloquent and polished speaker and he delivered the oration at the laying of the cornerstone of the Masonic Temple in San Francisco in June, 1860. The newspapers of the day laud the culture and eloquence of the speaker. He was a founder of the State Medical Society in 1856, and took a prominent part in medical meetings. As we have just observed, he was one of James King's doctors. His associates held him as one of the finest types physically and mentally of medical manhood.

There were many more doctors among the valiants of this period: A. J. Bowie, the silver-tongued orator, the founder of the Pathological Society, lived in a frame house which stood in its own garden on the corner of Stockton and Sutter streets, the lumber for which came around the Horn and its architecture smacked of the Shakespearean period. Bowie made this place a rendezvous for the intellectual element of the city. F. P. Wierzebecki, a Pole, was another of the founders of our medical institutions, he being one of the pillars of the medical societies of the county and state. He first wrote of the "California Fever," a confused type of all fever, including gold and ague, and, although ten thousand found their graves that first memorable year of the winter of '49 and the spring of '50, Wierzebecki did not lose a single case. It is interesting to note that the second edition of the book, one of the very first '49 publications in San Francisco, which he wrote: "California as it is, and as it may be, or a guide to the gold regions" which contains a chapter on "Medical Observations" upon the Californians, is now one of the most prized items in a California collection, being recently listed at \$600 in a book-lover's catalogue. Paper was not plentiful on the coast in those days, and the leaves of several of the copies were cut from wall paper. Washington Ayer was another scholarly man of this period. He lectured all the way across the Pacific, and on landing founded at Vernon, on the Sacramento River, one of the very first hospitals in California which underwent a tragic fate in the floods of that river.

Of a later vintage, but probably the greatest genius of his time, was Levi Cooper Lane, who

reached San Francisco early in the 60's to join his uncle on the staff of the first medical college. Dr. Lane was the recipient of more college degrees than has befallen any other medical man in California. From Union College, Schenectady, New York, A. B., A. M., and LL. D.; Jefferson Medical College, Pennsylvania, M. D.; London, M. R. C. S., and Berlin, Doctor of Medicine, "Summa Cum Honore." If degrees are any criterion of a man's greatness, which they aren't, his would be a worthy measure of his mettle. He was also the master of six languages, including Greek and Latin. In the latter, he composed his naval thesis, having been in the United States Navy before he came to California. He was also the author of an acknowledged surgical work on the head and neck. From the medical point of view his life was an ideal one, useful, and well spent, it being given to but few men to be as great as he was, "to be the means of helping to save human life and to diminish human suffering, to be a great doctor, a great philanthropist, and a great scholar as well as a religious and scientific man." When he died rich in years, St. Peter could worthily have said: "Well done, thou good and faithful servant—well done." He worked his way through college on twenty-five cents a week and lived to bequeath a million dollars to medical education, all of which he earned himself. It is only a few who die realizing their ambitions are satisfied, yet Dr. Lane succumbed in the seventies, having tasted the fruition of his own successful accomplishments, life's work completed and its hopes realized. Early in his manhood he had conceived the idea of fulfilling Dr. Cooper's idea regarding the founding of a medical school and a hospital for San Francisco. Although the latter lived to see his dream in part realized, he died long before it was an accomplished fact. And with his tragic and premature death his idea of a medical school seemingly vanished too, but its power survived in the ambitions of his nephew, Dr. Lane, and the latter toiled early and late to realize those dreams, and at length the time came when they materialized in the medical school which he endowed in the name of his uncle—"The Cooper Medical School"—thus proving that every truly great idea never perishes, but lives on to fulfill the destiny allotted it. Not content with this accomplishment, Dr. Lane founded the annual Lane course of lectures and the hospital and Medical Library which still bear his name, although overshadowed by another, and that is wherein the pathetic part of both Toland's and Lane's great gifts to humanity and to San Francisco lie. The identities of their progenitors are fast disappearing from the institutions which they founded. But perhaps Dr. Lane realized this eventuality, as his prophetic words delivered at the dedication of one of the medical college buildings, November 13, 1890, would seem to indicate: "Human memory has its limitations and we scarcely have a right to chide it for lessening its burden by dropping its distant links in the past; and it is probable that sharing the common fate of all things, the footsteps of coming years will obliterate the individuality of the work of which you are witnesses; yet the work itself will not perish," and in the immortal words of the martyred president, "shall not perish from the earth."

380 Post Street.

THE HISTORICAL COLLECTION OF THE LANE MEDICAL LIBRARY

By LOUISE OPHULS, Librarian

The splendid service the late Doctor Lane rendered Western Medicine in endowing Lane Medical Library, and the sane development of the nucleus under wise guidance until it now ranks with the best of medical libraries, is attractively sketched by Miss Louise Ophuls in this essay.—THE EDITORS.

THE idea of developing an historical section of the Lane Medical Library originated with Doctor A. Barkan. He had already endowed the section on ophthalmology and oto-laryngology. After bringing this section nearly to completion, so far as modern publications and periodicals are concerned, he began to collect all the historical material that might be available. During his travels in Europe he was able to find quite a few interesting volumes, but it soon became clear to him, especially when he consulted various experts on the History of Medicine, that it was a very difficult matter to restrict the historical part of the collection to one specialty. So, largely through the influence of Professor Sudhoff in Leipzig and Professor Sigerist in Zürich, he became interested in collecting material on the History of Medicine in general. He found that the authorities of Stanford University were quite willing to assist in this work, and he was also able to interest Professor Sudhoff of Leipzig sufficiently in this undertaking to have all further purchases for the historical collection made under his guidance and direction.

The largest part of the present collection was obtained in 1921, when there was an opportunity to purchase the historical library of Professor E. Seidel in Meissen. Professor Seidel had spent his life in collecting books on the History of Medicine. He was especially interested in Arabian medicine and, therefore, his collection contains a great many Turkish, Persian, and Arabian manuscripts. But in addition the rest of the History of Medicine is well represented. It was Professor Seidel's wish that his collection should be kept together and if possible well-housed in connection with some teaching institution. At Doctor Barkan's request, he wrote a short vademecum, explaining and enumerating the volumes in his historical collection. The vademecum has been translated and will be published shortly.

Since the purchase of Professor Seidel's library, many interesting old books have been added to our collection and we have endeavored to purchase all modern books on the History of Medicine, and all publications which would facilitate a study of the available material.

The following may serve to give an idea as to the extent of our collection. It is, of course, impossible to go into detail; only a few of the most important works can be mentioned.

The most unique part of the Seidel collection is without doubt that consisting of the Turkish, Persian, and Arabian manuscripts. The oldest and rarest of these manuscripts is a set of two volumes in three parts of a large compilation on general medicine. This system was written at the end of the thirteenth century and is said to have contained eighty-eight volumes, of which we own volumes 32 and 33. Professor Seidel, in his vademecum, calls these volumes "Unikum," as they are supposed to be

the only copies in existence. There is also a manuscript written in 1466 on "Remedies," which is well preserved. Most of these manuscripts are written in red and black ink. As Professor Seidel wrote and read all the Oriental languages, he made many annotations in Turkish and Persian on the margin of the books which, of course, enhances the value of the collection. Besides manuscripts on materia medica, veterinary medicine, surgery and medical dictionaries, this collection contains Turkish and Persian prayer-books, and a very beautiful illuminated Koran. Grammars, dictionaries—in short, all helps necessary for the study of Oriental languages accompany this most remarkable collection. In his vademecum, Professor Seidel gives a full and interesting account of this section of his library, giving the names of the authors and the contents of their works.

Owing to Professor Seidel's great interest in Arabian medicine, he made a special effort to have this part well represented, and we find many beautiful editions of Avicenna and Rhazes in all languages. Among them is the famous "Canon medicinae" of Avicenna in the Arabian language. Beautiful editions of Haly Abbas, "Liber totius medicinae," Lugduni, 1523; Isaac Judaeus, "De diaetis universalibus," Basileae, 1570; Albucassis, "Methodus medendi," Basileae, 1541; Avenzoar, "De medica facultate," Lugduni, 1531, and Averrhois, "De re medica," Lugduni, 1537, are among the treasures of this part of his library.

Of medical incunabula the library possesses only six. Of these the best preserved and most beautiful is a copy of the "Liber Rasis ad almansorum," Venetiis, 1497, Hain 13893, printed in gothic letters in two columns with illuminated initials. Then there is a set of two volumes of the "Canonis" by Avicenna, Hain 2214, which is well preserved and has the original binding. The other three, a "Pratica," by Serapionis, J., Venetiis, 1497; "De lumine maius," by Manlii Joh. Jac., Venetiis, 1496; "De aialibus," by Avicenna, no date, Hain 2220, have excellent paper and clear print.

The Greek authors are well represented. We have a very fine copy of the complete works of Hippocrates in Greek and Latin, the Frankfurt edition, 1595, which was edited by A. Foesius. Text and translation of this edition are, according to Choulant, the best in existence, and he also considers the annotations by Foesius very valuable. This edition was reprinted in Genoa in 1657 by Chouet, and in it are glossaries by Erotian, Galen, and Herodot. Furthermore, we find a very costly edition by Charterius, "Magni Hippocratis Coi et Claudii Galeni Pergameni, Opera," Paris, 1679, in fourteen volumes, which was begun in 1638. When Charterius died in 1654, ten volumes had been completed. The last four volumes of this edition were finished by Blondel and Lemoine in 1679 and paid for by the son-in-law of Charterius, Charles du Gard. The edition is bound in nine folios and a few of the first volumes have the original title page dated 1639. Another very interesting set of Hippocrates, "Opera omnia," Greek and Latin, and edited by van der Linden, printed in Lugduni, Batavorum, 1665, has on the flyleaf of each volume the inscription, "March, 1864. Purchased at the sale of my

dear friend Thackeray's books," W. H. Russell. It also has on each title page the embossed monogram of Mr. Thackeray. This copy is one of the valuable books which came to us from Dr. Levi Cooper Lane's personal library. We also have the well-known edition by C. G. Kühn, Lipsiae, 1825, in three volumes; the French translation by Littré, Paris, 1839, in ten volumes, and a very good German translation, with important annotations by J. F. C. Grimm, printed in Glogau, 1837. Of the single works of Hippocrates we have the Greek and Latin edition of the aphorisms edited by Opsopois, 1587, and the edition printed in Amstelodami, 1685, and edited by Theod. Janssonio. Many commentaries on Hippocrates, written by different authors, complete our Hippocratic collection.

Then there are the works of Aristoteles; Nicander's "Theriaka," edited by Gorrhaevus, Paris, 1557, and Florence, 1764; the latter edition of the poem has Greek, Latin and Italian text. The translation of Dioscoridis' work, "De re medica materia libri sex," by J. Ruellius, Lugduni, 1596, and one by P. And. Mathiolus with famous commentaries by the translator, published in Venetiis, 1565, with beautiful illustrations, in folio, and the original tooled leather binding with metal clasps; the commentaries by Amati Lusitani, Lugduni, 1558, and the Alphabetum empiricum, Tiguri, 1581, are also at hand. Of other Greek authors, such as Areteus, Soranus of Ephesus, Moschion, Xenocrates, we have very good editions. Galen also is well represented by the Latin edition in eight volumes, Basileae, 1542; the fifth edition, Venetiis apud Juntas, 1576, in eight volumes; the Greek and Latin edition by C. G. Kühn in twenty-two volumes, Leipzig, 1821-33, and many others. There are many beautiful old editions of various works by Oribasius, Basileae, 1529, and Aetius, translated by J. Cornarius, Basileae, Froben, 1542. The complete works of Aetius are also contained in the Stephani collection, "Medicinae artis principis," Paris, 1567, and also the complete works of Alexander Trallianus, translated by Guinterius. Paulus Aeginata, "Libri septem," Greek edition, Basileae, 1538, Latin translation by A. Torinus, Basileae, 1532; Psellus, "De victus ratione," Basileae, 1529; "De lapidum virtutibus," Lugduni, Batavorum, 1745, may also be consulted, and many others of the same period.

The Latin authors are also well represented. Our collection of these includes Celsus "De re medicae libri octo," Lugduni, Gryphium, 1542 and 1654; Amstelodami, 1687-1713; Batavii, 1722; Coelius Aurelius, "Tardarum passionum libri 5," first edition Basileae, H. Petrus, 1529, and the Amstelodami edition, 1709, which is considered the best; Serenus Samonicus, "De medicina praecepta saluberrima," Amstelodami, 1662, and Constantinus Africanus, "Opera," in two volumes, apud H. Petrum, Basileae, 1536.

The regimen sanitatis Salernitanum, the famous poem of the school of Salerno, was written originally in 364 verses, but was much enlarged later and some of the more recent editions contain more than 1000 lines. The origin of this poem is not known. It was written for the layman, not for the physician, is in popular style, and contains excellent hygienic rules. Many editions of this poem in all

languages, Latin, English, French and German, are in our collection; the oldest of these is the Latin edition published at Frankfurt in 1612.

The medical collections are interesting, not so much for the writings of the individual authors, as by showing the trend of medical knowledge of a certain period. The Articella collection, of which we have the 1525 edition, published by Anton du Ry of Lugduni, gives us a good idea of the writings of the ancient physicians most popular in the Middle Ages. It contains commentaries on the writings of Hippocrates, Galen, Celsus and others. It is a small volume with red and black title page, with ornamental border. The two most famous collections containing works on medicine by ancient authors, the *Collectio Aldini* and the *Collectio Stephaniana*, are both in the library. The *Collectio Aldini* was printed by the famous Aldus press in Venice in 1547 and has illuminated initials. The *Collectio Stephaniana*, Frankfurt, Fugger, 1567, is in two volumes and contains writings by Aretaeus, Rufus of Ephesus, Alexander Trallianus, Paulus Aeginata and others. Both these editions are rare, according to Choulant. We also own some old medical dictionaries; as, for instance, the *Stephani dict. medicum*, Fugger, 1564; the *Castelli lexicum medicum*, Batavii, 1792; the *Kühnii lexicon medicum*, Lipsiae, 1832, which are all valuable helps in explaining the medical terms used by the physicians of ancient times. There are also the so-called *Crassi collectio*, "*Medici antiqui graeci*," Basileae, 1581; the *Haller collectio*, "*Artis medicinae principes*," Lausanne, 1769-1774; the *Kühn collectio*, Lipsiae, 1821, and the Dietz "*Analecta*" and "*Scholia*," Lipsiae, 1833, and *Regimonti*, 1834, and many other more modern collections. "*Collectio scriptorum de febribus Venetiis*, 1576; "*Collectio chirurgica veneta*," Venetiis, 1546, apud Juntas, having the title "*Ars chirurgica*" and containing writings by Guy de Chauliac, Teodorico, Lanfranchi, etc., are some of the collections on special subjects. Vidi Vidi, who published the *Collectio chirurgica Parisina*, Paris, 1544, apud Galterium, added commentaries to the writings. The *Collectio Gynaeciorum*, edited by S. Spachius, Argentinae, 1597, and the *Collectio "De Balneis"*, Venetiis apud Juntas, 1553, are beautifully printed and preserved and are also said to be rare.

Of the works of Vesalius, the founder of modern anatomy, we have several important editions. There is a well preserved copy of the first edition 1543 of the "*De humani corporis fabrica*" in the original binding. The title page was missing, but a reprint from the original wood block has been substituted. This cut shows Vesalius standing near a table on which a female body is lying which he is about to dissect. He is surrounded by a large group of spectators. The drawings for the magnificent wood cuts throughout the book were made by Joh. Stephan von Calcar, a pupil of Titian. In the second edition, published in 1555, which Vesalius himself prepared for publication, the text is elaborated and a few wood cuts are added, also the frontispiece is slightly changed. This volume is beautifully bound in wooden covers with embossed leather back, the binding being very well preserved. At the end of the volume is the large handsome printer's mark, "Arion on the dolphin." The very beautiful edi-

tion, "*Opera omnia anatomia et chirurgica cura*" H. Boerhaave et B. S. Albini," Lugduni Batavorum, Verbeek, 1725, in which the original wood cuts have been replaced by copper engravings by Jan Vandelaer, is also in the library; also the "*Compendiosa totius anatomie delineatio, aere exarata*," per Thomas Gemimum, London, 1545, which is an early copy of Vesalian illustrations. This volume has, instead of the original title page, one with allegorical figures and in the center the English coat-of-arms. The two nude figures from the epitome are in this edition, otherwise it has the plates of the *Fabrica*. The copper plates are very clear and are said to be the first copper plates made in England. As Gemimum was an engraver, he is supposed to have designed the new title page. A reprint of the text of the epitome, with commentaries by N. Fontanus and with fewer and poorer plates, published in 1642 in Amsterdam, forms part of our Vesalian collection.

Many works of the famous physicians of the Renaissance Paracelsus, Servetus, Fallopius, Ambroise Paré, Cesalpino, Fracastoro are in our collection.

The seventeenth century physicians are represented by such famous writers as Harvey, Malpighi, Borelli, van Helmont, Thos. Willis, and Thomas Sydenham. Our collection of the publications of eighteenth century authors contains such names as Boerhaave, Albrecht von Haller, Ramazzini, Alexander Monroe, Thomas Soemmering, Albinus, Scarpa, Smellie, John and William Hunter, Leopold Auenbrugger, Morgagni, Edward Jenner, etc.

We are glad to be able to state that we have a very complete collection of the works of the famous men of the modern period.

We subscribe for most of the journals dealing with historical subjects, such as the *Annals of medical history*, *Chicago society of medical history*, the publications of the *Charaka club* in New York, the *Janus*, *Société d'Histoire de la médecine*, *Schweizerische Gesellschaft für Geschichte der Medizin*, *Archiv. Mitteilungen und Studien zur Geschichte der Medizin*, and we have complete sets of most of these.

A vast number of biographies and bibliographies are also available, also facsimile editions of some of the old classics with annotations and commentaries.

We have a large section containing books on the history of medicine in all languages. Here you will find the texts of Garrison, Baas, Haeser, Pagel, Sudhoff, Puccinotti, Daremberg, Sprengel, Neuburger—in short, all the authorities on medical history. Books dealing with special subjects are Choulant's history and biography of anatomical illustrations, in the original and also in the splendid English edition by Mortimer Frank; Leclerc, L., *Histoire de la médecine Arabe*; Fasbender, *Geschichte der Geburtshülfe*; Hirschberg, *Geschichte der Augenheilkunde*; Politzer, *Geschichte der Ohrenheilkunde*; Sudhoff, *Geschichte der Chirurgie* and *Geschichte der Syphilis*; Gurlt, *Geschichte der Chirurgie*, and many others. One of our aims is to get together all the helps to facilitate the study of the history of medicine.

As stated above it is, of course, impossible to give in such a short paper an idea of the wealth of material contained in our collection. I only wish to draw

the attention of the members of the medical profession to this department of our library, in the hope that sooner or later some of them may become interested in this fascinating subject. In conclusion I will quote from Dr. Seidel's vademecum the words with which he closes his manuscript:

Vivat, floreat, crescat in aeternum Universitas
Litterarum Pacifica! Q D M O bene vertat!

Goiter in the Intermountain Region of Utah—The larger phase of the goiter problem, and the one that may prove to be most significant in the future, George W. Middleton, Salt Lake City (Journal A. M. A.), says is the relative iodine deficiency in the various geological strata that form the catchment basins and water-sheds of the streams. If this were determined in any given section, one could at a glance estimate the probable goiter incidence and the extent of prophylactic measures necessary to meet the situation. Theoretically, all volcanic or granitic sections of country should have a relatively large percentage of goiter incidence. Whether this is the case or not remains to be proved, but in the data available in the intermountain region of Utah there is at least a marked indication in that direction. Thus, in the town of St. George, in southern Utah, with a population of more than 3000, goiter was quite unusual for more than half a century, from the time of its founding until a water system was installed and the water from Pine Valley Mountains brought in. Pine Valley Mountains are almost entirely igneous, and the volatile iodine no doubt escaped at the time of their extrusion. Since the advent of the new water supply, many people have developed goiter, and what was for a long time a comparatively immune district has now been added to the large endemic section of southern Utah. In the Virgin Valley, which is a part of this section, fully 75 per cent of the adult women have goiter. It is here, in these isolated mountain gorges, that one encounters enormous thyroid growths, which are allowed to progress unchallenged until they assume maximal dimensions. It seems to be well established by the statewide survey now in progress that towns which enjoyed considerable immunity from goiter while they used well water, and water from the surface springs, are taking on a marked increase of goiter incidence since they installed water systems, and are getting their water supply from mountain springs up near the melting snows. During the last three years Middleton has treated 333 cases of the various forms of goiter, not including hypothyroidism or the inflammatory conditions. One hundred and fifty-six thyroidectomies were performed with two fatalities, a mortality of 1.3 per cent. Seventy-three per cent of these patients were toxic, and many of them extremely toxic. One of these fatalities was due to tracheal obstruction, and one patient was so toxic that she showed no improvement after months of rest and medical treatment, and thyroidectomy was undertaken as a last resort. Middleton believes that rest in bed with abundance of fluids, and the use of compound solution of iodine in the hyperplastic cases, are the most important preparatory measures. Except in cases with broken compensation, pre-operative digitalization has been of little value. Calcium carbonate is given to prevent tetany. The condition described as hypoglycemia has been encountered five or six times. Urinalysis showed much acetone and diacetic acid. The relief from intravenous glucose was striking.

Do You Know—

That insanity, epilepsy, "nervous prostration," feeble-mindedness and criminalistic tendencies are inherited?

That virtue, intelligence, beauty, social capacity, capacity to succeed in life, capacity to make money, tendencies to become a church-goer, tendencies to become a good housekeeper or a good father or mother are all largely matters of heredity?

That most popular ideas about "prenatal influence" are complete bunk?—A. E. Wiggam.

THE HISTORY OF THE DEVELOPMENT OF WOMEN IN MEDICINE IN CALIFORNIA

By ADELAIDE BROWN, M. D., San Francisco

THE history of the development of women in medicine in California covers a period of fifty years if one begins with the professional women who continued in active practice for more than twenty-five years.

The opportunity for medical study was refused to women in California as long as the medical schools were owned privately, but as soon as the Toland Medical School was given to the University of California to become its medical department, as co-education was the policy of the University, the medical school accepted Dr. Lucy M. F. Wanzer* as its first woman student. Dr. Wanzer graduated in 1876. Very soon the College of the Pacific, later Cooper Medical College, removed its restrictions and Alice Higgins graduated in 1877 and Anabel McG. Stuart in 1878. Dr. Stuart practiced in Santa Rosa for about forty years. Thus barriers fell.

But attaining a medical education was by no means impossible to a Californian inspired to work in this line. In 1872 Charlotte Blake Brown left her home in Napa, California, and graduated at the Woman's Medical College in 1874 in Philadelphia. Dr. Brown spent her senior year as a hospital intern to gain practical training and returned to California to begin practice in San Francisco, imbued with the importance of hospital experience to both graduates and medical students.

The Pacific Dispensary for Women and Children, renamed and incorporated in 1885 as the Children's Hospital and Training School for Nurses, was founded in 1875 and was the finite expression of this ideal. Associated with Dr. Brown in the pioneer years of this work were Dr. Martha Bucknall and Dr. Sarah E. Browne. They called on seventy women to gain the names of eight for the first Board of Lady Managers. In 1880 the Training School for Nurses was established, the first on this western coast, and was again a practical expression of the deep interest in the welfare of the individual patient which was characteristic of the early women physicians.

Charlotte Amanda Blake Brown was born in Philadelphia in 1846, where her father, a Bowdoin College graduate, and later a minister, had a boys' private school. Her father came to California in 1850, where he established a boys' school in Benicia. His wife and family followed in 1851. They crossed the Isthmus carried by Indians and lived in California three years. Then the father was called to Chili as a preacher to Cornish miners and the family lived there four years. En route they were blown out of their course and visited Tahiti. These years in the Southern Hemisphere, associated with an interest through life in the work of Missions, gave Dr. Brown a remarkable international sympathy. She did medical work through her life for the Chinese women in the Missions in San Francisco and for the American Board of Foreign Missions by caring

* (A complete Life of Dr. Wanzer is given by Dr. Emma Sutro Merritt, as a contribution to this historical number.)

for returning missionaries and their families. After returning to New England she graduated, at 20, from Elmira College, New York, one of the earliest colleges to grant degrees to women. She came to Arizona with her father and mother, where her father had been ordered as chaplain with his regiment at the close of the Civil War. There she met Henry Adams Brown of Riverside, Maine, and was married in 1867. The young couple crossed the desert with a troop of soldiers at a time when Indian raids were common and ruthless and white men said to a woman, "The first bullet will be for you if we are attacked." The young couple settled in Napa, California, where after the birth of her second child she read anatomy seriously with her preceptor, Dr. Charles (?) Nichols. For their faith in her ambitions enough can not be said for the co-operation of her husband and parents. She lived not only to lay the foundation and see the structure (other than bricks and mortar) rise of a great hospital, but to give to a home and three children every opportunity a sympathetic, intelligent and far-seeing educated woman has in her power to give home and children.

Charlotte Blake Brown.

Another woman physician always rises before me as I think of the early women in medicine, the creative women physicians they were.

Elizabeth A. Follansbee was a friend of Charlotte Blake Brown's in Napa, then working as a teacher in the Napa Seminary for Girls. Dr. Follansbee was born in Dorchester, Mass., was the daughter of a prosperous sea captain and was taken to Paris for

her education. She was a woman of delicate health, great grace and charm of manner and of the most refined taste and ideals. She followed Dr. Brown to Philadelphia, though she matriculated at the Medical School of the University of California. After graduation, in 1877, she was associated with Dr. Brown in work in the Children's Hospital. Dr. Follansbee was obliged, on account of her health, to seek a warmer climate and settled in Los Angeles in the early eighties. There her personal qualities won her the friendship of the leaders in medicine and she was asked to take the Chair of Pediatrics in the Los Angeles Medical Department of the University of California, which she held until the school was closed.

Dr. Follansbee was a friendly critic of her women students and a recommendation by her of a candidate for internship in the Children's Hospital meant much more than scholarly attainment. She was a devoted friend to her patients; of herself she thought least of all. She was never rich in this world's goods, always too busy to keep books and too unselfish to send the bill if she suspected it would be difficult to meet. She was an idealist and held the torch high. Her students had the art of knowing and considering their patients thoroughly presented to them.

C. Annette Buckel, who came to California and settled in Oakland in 1877, brought to her chosen work the richest of human experience. She was born in western New York State in 1833; an orphan at 6 months, she was brought up by her grandparents. She taught, to earn the money to go to the Woman's Medical College in Philadelphia, where she graduated in 1858. She was associated with Dr. Elizabeth and Emily Blackwell in New York, the pioneer women physicians in the United States. She later went to Chicago, where she started practice. In 1863 she was commissioned by Governor Morton of Indiana to go South, to be responsible for Indiana's soldiers in hospitals along the Mississippi. She was the head of an army nursing service. It has been most interesting to read over passes signed by General Grant and General Graham, letters of instruction of which this is an example: "The appointment of female nurses by the surgeon in charge of general hospitals upon the recommendation of Miss Buckel will be confirmed by this office." Signed "I. M. Barnes, Acting Surgeon-General." This order followed in two days, a letter from Dr. Buckel suggesting "that at one general hospital, Jeffersonville, selected nurses could be trained and passed on to other hospitals, thus avoiding the annoyance given surgeons by the continued applications for situations by women stragglers and securing more valuable assistants in hospital nursing."

From army experience Dr. Buckel went to Boston, where she was associated with Dr. Marie Zakrzewska in the New England Hospital for twelve years, and then after two years' study in Paris and Vienna she came to California. Dr. Buckel was eminently a citizen of the community in which she lived. She was interested in and contributed to the scientific life of Oakland and was one of the founders of the Home Club, under whose auspices and largely through her inspiration certified milk became possible in California.

She was always interested in child nurture and at her death in 1912 she left her property to be used for a fellowship in child psychology, especially the study of the feeble-minded children. This legacy was accepted by Stanford University and has been used steadily in this field of work. Several of our state institutions have profited by the work of students who were Fellows of the C. Annette Buckel Foundation, Stanford. Dr. Buckel was always the center of an intellectual group, progressive in the highest sense of the word. Her personal experience has been broad and hers was a lovely exterior, a dignified, beautiful woman, generous, kind and able in her professional work. Her home circle often contained those she was re-educating to live, with the infinite patience this work needs.

These three women in medicine were lifelong friends and an inspiration to each other. Together they created a standard for intellectual and professional attainment that left little for the women who came after them to add.

The adoring eyes of the child focus themselves on the mother-doctor. After twenty years the adult sees in the professional career of that mother a life characterized by undaunted courage, glorious optimism before which difficulties vanish as does our fog before the sun, and a clear vision of the future for women united with a love of her kind. Medicine offered her the great opportunity for self-expression. Dr. Henry Gibbons Jr. wrote at the time of her death in 1904: "To few souls has it been given to live to see the attainment, personally and professionally, of their heart's dearest wishes."

In retrospect, these pioneer women physicians were of noble pattern. Each one brought to her work unusual qualities and experience and freely gave in her professional life.

In the next group of women physicians extending to today, I have selected those who stand out as creating new fields of activity for women and milestones, therefore, in any history of women in medicine in California.

Dr. Mary B. Ritter (Cooper Medical School, 1886) served as the first woman physician and lecturer to women students at our State University. Today the work requires the services of several women physicians and there is no college, normal or high school but retains if possible a woman physician for the care and instructing of women students.

Public health in executive and laboratory fields has had the services of California women in national and state positions.

Anesthetics as a specialty for women physicians attracted Mary E. Botsford (Medical Department, University of California, 1896), and her skill and generous patience have given the necessary training to many women as well as men who followed this line of work.

Pediatrics early attracted women physicians in California; as service to sick children, they created the Children's Hospital; as service to keep children well, the establishment of certified milk and the well baby centers attest their interest in the community. Dr. Emma Sutro Merritt, on her return from Paris in 1887, was at the head of the Department of Surgical Pediatrics in the Children's Hospital, where she continued until extensive business responsibilities compelled her to resign her medical work.

Surgery has been a field where success has been attained by a considerable number of women. The opportunity to operate was given at the Children's Hospital and early, the light hand, the detailed after-care, the careful consideration of the environment and life-strain of the patient and the sustained after-interest in the convalescent made for successful results at the hands of women surgeons.

Competition is closer and perhaps the burden of proof heavier in this particular field, but the reputation and success attained by Dr. Charlotte Blake Brown and Dr. Florence Saltonstall Ward in San Francisco and by Dr. Rose Bullard in Los Angeles show that they had progressed far, from the days when a leading surgeon said to the pioneer woman surgeon: "Perhaps you will be *allowed* to operate on poor patients, but you had better send your pay patients to me."

Obstetrics has always been a field where all women physicians have given steady service. In the new development of the hospitalization of obstetrical cases in San Francisco, the Alexander Maternity of the Children's Hospital was the pioneer in the field. The donor, Mrs. Charles B. Alexander, desired to offer to self-supporting families of moderate means the nursing care and protection of a hospital at reasonable rates. This house service has developed both leadership in the consultants responsible for it and has given excellent educational experience to the interns who conduct all normal house cases.

Dr. Edna Field (Cooper Medical College, 1883) developed this work.

Prenatal care, breast-feeding and post-natal examinations were cornerstones of this obstetrical service always. A careful analysis of indications based on a study of each case antedated all operative obstetrics.

Thus, the development of women in medicine in California centers about the development of their medical center at the Children's Hospital. Opportunity was thus early given them to meet and to learn to meet responsibility in medicine. The interns were always women. For many years the Children's Hospital gave the only opportunity in the West for an internship for women. Then, as competitive examination won appointments, women students came into their own, and here in California in recent years rank attained as students has placed women as interns in the University of California and Stanford hospitals; while the Children's Hospital has drawn from other institutions stretching from the universities of Edinburgh, Liverpool, Johns Hopkins, to Oregon and British Columbia. Ten or twelve interns annually take the rotating service and go out to medical work throughout the United States and in the mission fields of India, China, and Persia.

The spirit of shouldering responsibility was paramount in the women of the first forty years in medicine; each one was in the position, practically, of the country doctor who simply had to make good for every case. Each woman felt not only the urge to care for her patient well, but to score for women in medicine.

In the last decade women physicians have taken positions in the California medical schools of various

teaching ranks. Quality and sincerity in work and an endowment as a teacher are requirements. Obstetrics, gynecology, pediatrics, and neuro-psychiatry are the fields of teaching covered.

Two groups of women physicians deserve special words. The group who have added to the profession of wife and mother, an active life in the medical profession. It is no doubt a taxing combination and means a mentality that can evaluate and choose, and also an atmosphere at home, sympathetic to the effort. But that it *can* be done, the homes, children, and professional success of many women physicians in California go to prove.

The second group contains the devoted followers of general practice, the family doctors who follow the lives of the family groups from birth through childhood, adolescence, and maturity, and start out a new generation in turn. In this group most of the women physicians of the first four decades in California have functioned. As rural and urban physicians with a personal understanding and interest in the individual problems of their patients, they may in the future fill the demand as yet unanswered for the general practitioner.

No history of the development of women in medicine in California would be just or complete without a word of recognition and appreciation of the steady, helpful co-operation and sympathy given individually and collectively to women physicians by our brothers in the profession. At the time when women first applied and were excluded by the San Francisco County Medical Society and caricatured as "Carrie Nations" in the News Letter of that week, Dr. Samuel Morse, rising from a sick-bed, proposed, and Dr. Henry Gibbons Sr. endorsed, their names. Such men were heroes.

That year the women were admitted to the State Society, and the San Francisco County Society later admitted Dr. Lucy M. F. Wanzer, and thus the ice was broken.

The names of Dr. Samuel F. Morse, Dr. Henry Gibbons Sr., Dr. Henry Gibbons Jr., Dr. Levi C. Lane, Dr. Geo. Chismore, Dr. Chas. E. Blake, Dr. L. L. Dorr, Dr. Douglass Montgomery, Dr. Harry M. Sherman, Dr. John F. Morse, and Dr. C. A. Von Hoffman stand out as helpful friends of women in medicine at a time when it took courage to announce such a position. As consultants and members of the staff of the Children's Hospital, they gave support and endorsement to the work of women.

To the second fifty years of women in medicine in California is given the privilege of "carrying on." The profession has made marvelous advances; a college degree is today a prerequisite to the study of medicine with a very specific preliminary requirement as well. An internship is included in California before the degree Doctor of Medicine is granted.

The younger group begin where we leave off, but pioneer women physicians have set a marvelous standard in creative work and, in the spirit of service to suffering humanity, not easily surpassed. The early women physicians not only blazed a trail, but, well equipped educationally and in life experience, they made it a goodly highway easier of transit for every woman who follows, for their attainments.

909 Hyde Street.

SOME CORRESPONDENCE RELATING TO THE INTRODUCTION OF VACCINATION INTO AMERICA

By WALTER C. ALVAREZ, M. D., *San Francisco*

SEVERAL years ago while rummaging in an old book store in New York I picked up, off of a pile of rubbish being swept up for the furnace, an old correspondence-box which had attracted my attention. On opening it, what was my delight to find a letter from Jenner dealing with one of the first shipments of vaccine to Benjamin Waterhouse in America; two long letters from Waterhouse in regard to this vaccine; a letter from Dr. Holyoke; lecture cards from three professors at Harvard Medical School in 1798-1801, and the diary and notes of a young medical student by the name of Matthias Spalding. This young man had been a student in Waterhouse's office and at Harvard, and had then gone to England for post-graduate study. Unfortunately for us, he was not much of a diarist and his entries too often are short and perfunctory and of the "Got up, washed and went to bed" variety. The one incident of the day which seems always to have interested him, judging by the fact that he seldom omitted reference to it, was—his dinner! Such as it is, however, it gives us interesting glimpses of the life of a medical student in the London of that time.

He arrived on May 18, 1801, and observed that "It was a noisy and disagreeable place." After a walk around the city, he could see that "The people looked and acted pretty much like other folks—all appeared to love money." The next day he "Dined with old Mr. Bainbridge and toasted the King, Queen and Royal family, Mr. Gray, George Long and Earl St. Vensen; had tea at 8 o'clock; then rose from the table and staggered home." Later he apparently did not feel so proud of this exploit, because we find "staggered" crossed out and "went" written above it!

On May 30 we find this *medical* student attending lectures on bleaching silk, on agriculture, the physiology of plants, astronomy, etc. On June 9 he writes: "Attended Mr. Garnett's lecture on the physiology of plants, but during the lecture attended more to the physiognomy of animals, for directly opposite me was a most beautiful young lady. She had an enchanting smile—her eyes sparkled like fire and I, or my eyes, could not help catching the flame. I was attentively engaged, but lost my lecture." Apparently his affections had not yet been put in cold storage, where Dr. Osler believed those of the medical student should be.

A good bit of medical psychology is found in his notes on a visit to the inoculating hospital in London. He says: "When inoculated, Woodville gave these children 5 gr. of Rhei and ordered 5 gr. more to be taken in about a week, *principally to quiet the parents.*" (*Italics mine.*) "He seldom tells the patient whether it be smallpox or cowpox, as many of them still have some prejudices respecting the matter."

After he had had a good look at the sights of London he made his pilgrimage to Cheltenham, where Jenner had him to dinner several times and

took him with him on his rounds to the poorhouse where patients were treated and vaccinated. Later he dined with Jenner a number of times in London. Unfortunately, he gives us none of his impressions concerning the great discoverer of vaccination, and the entries in the diary are all too brief.

In October, five months after his arrival, Spalding decided that he would settle down to work. He paid £20/0/0 for the privilege of being a "Surgeon's pupil," and for £11/10/0 more he did dressings under Mr. Cline. Sir Astley Cooper's courses in surgery cost him £6/6/0. His careful notes on these lectures show the remarkable absence of specialism in those days. Mr. Cline on one day removed a stone from the bladder and on the next, a cataract from the eye. The man who gave the course in midwifery lectured also on physiology. Spalding studied obstetrics, anatomy, surgery, chemistry, medicine and a little dentistry. His tuition for the year amounted to £77/0/0—a large sum in those days. Under the heading of amusements, he lists "Went to Bethlehem (since corrupted to Bedlam) near Moorfields to see the mad people." This cost him £0/3/6. Apparently there was a charge of £0/2/6 for every confinement he was allowed to attend.

In the correspondence-box, together with the numerous lecture cards, there was a large, neatly written manuscript report of Astley Cooper's lectures which cost him £1/12/0. Apparently, even in those days needy students made money by selling their notes to their less industrious fellows. Cooper begins his lectures with the statement that "Formerly a surgeon was only thought to require a lion's heart, an eagle's eye and a lady's hand, but he is now allowed to have some *brains*."

A carefully kept cash account gives us a number of interesting sidelights. All doctors in those days carried a gold-headed cane and his, we find, cost £1/6/0. A "thermometier" cost £0/13/0, an inoculating lancet £0/1/6, etc. Surgical instruments were £20/0/0. At one time he was ill for sixteen days and his doctor's bill, including that for medicines, was £15/15/0. Apparently no allowance was made for his being a post-graduate student. Either he was somewhat of a dandy or else he laid in a goodly supply of "cloathes," because he paid his tailor £68/11/0 in a year and a half.

Before turning to a description of the letters found in the box it may be of interest to know that Matthias Spalding settled in Amherst, New Hampshire, where he became a successful practitioner. He had a good deal to do with popularizing the practice of vaccination in America, and in 1817 he was given an honorary degree of M. D. by Dartmouth College. There is a biographical sketch of Matthias on page 125 of "The Spalding Memorial" (Chicago Medical Publishing Association, 1897). He is mentioned approvingly by Oliver Wendell Holmes on page 108 of his "Prize Dissertation on Intermittent Fever" (Boston, 1838).

Having now been introduced to the original owner of the documents we can proceed to a discussion of the three most interesting letters. The two from Waterhouse are valuable because they show so clearly the difficulties which he encountered in keeping a proper supply of vaccine matter on hand in those days when it had to be obtained either on

threads or from the pustules on the arms of the vaccinated. At times he even had to pay people to let him vaccinate their children so that he could keep the virus going. He was one of the organizers of Harvard Medical School and one of the most interesting characters in American medicine. The best biography of him which I have found is by W. M. Welch in the proceedings of the Philadelphia Medical Society (1885, vii, 172). He obtained much of his data from an article by Martin in the North Carolina Medical Journal for January, 1881. Perhaps the best insight into the character of the man can be obtained by reading his tracts on vaccination, letters from him published in Baron's Life of Jenner (London, 1888, vol. I, pp. 439, 473 and 593), and letters published in the biography of Lyman Spalding. Lyman belonged to another branch of the same Spalding family and was a resident pupil in Waterhouse's home a few years before Matthias was there.

We learn from these sources that after several unsuccessful attempts to obtain active virus from England, Waterhouse at last got some and vaccinated his children. His troubles then began. He was soon deluged with demands for virus and for information. From letters in the volume on Lyman Spalding we learn that he had difficulty in his efforts to make the thing pay. Many of those to whom he gave the virus neglected his instructions; got it contaminated with smallpox and other things and discredited the practice. Others tried to belittle him and to take all credit for themselves. As always, many denied the efficacy of the new treatment in spite of the very convincing experiments which were carried out in Europe and America. It should be noted, however, that the more intelligent physicians and laymen almost immediately accepted these proofs and helped in the dissemination of the practice. As Waterhouse wrote to Jenner (Baron, vol. I, p. 473): "The characters in America most distinguished for wisdom and goodness are firm believers in your doctrine. They are not, however, overforward in assisting me against this new irruption of the Goths—. At present they leave me too much alone and it is probable will only come openly to my assistance when I do not want them. Had I not a kind of Apostolic zeal, I should at times feel a little discouraged. The natives of America are skilled in bush-fighting."

The jealousy and opposition of his medical brethren; the distrust that the layman feels for an innovating physician (never for an innovating quack); his own preoccupation with a large correspondence and his research on vaccination soon left him without patients and in actual want. Dabbling in politics added to the number of his enemies, and in 1812 he was forced to resign his position at Harvard. In many ways he undoubtedly was one of the big men in American medicine, but he seems to have been rather pugnacious and tactless, and many of his troubles were probably brought upon him by himself. According to Baron (vol. I, p. 442) the idea of obtaining virus from vaccinated cows was original with him.

Following are the two letters which were both directed to Spalding in London:

Dear Sir:—
"Cambridge, Oct. 20th, 1801.
I rec'd your letter by the Galen together with the

spectacles, glass, etc., and was very well pleased with them, and hereby return you my thanks for executing your commission so much to my entire satisfaction.

I was gratified at hearing of the polite attention of Dr. Lettson to you, and I rejoice as often as I call to mind the fortunate incidents that have combined to place you in the high road of improvement you are now in. You will learn more in one week in London, than in America during twenty.

Your second letter was from Cheltenham, where altho it carries you from the lectures must nevertheless be improving to you. A prudent man can draw instruction from every place. The conversation of learned, polished and agreeable men is more valuable than books. They are the '*living manners*' and are always useful. Air, earth and the congregation of men are the pages for a young physician to study, and as there is scarce any book out of which something useful may not be drawn, so there is no situation from which something may not be learnt. I presume you will spend the winter in London, if so, you can attend the anatomical and chemical lectures to advantage. I was pleased to hear that you had conversed with the man I so much admire, I mean Jenner. Present my best regards to him and tell him that although I sought his life with eagerness, and failed in the attempt,¹ I have nevertheless (instigated by the same spirit) been a little consoled in *hanging him up, in effigy*, in my parlour.

Aspinwall,² whose candor and liberality was all affection, has shown his teeth this summer and has injured the new inoculation by inoculating those *whom he knew had never gone fairly through the disease*, and advertising the result in the newspapers. It was just his harvest time, it staggered several who were balancing between the S. pox and kine pox, and occasioned perhaps 20 or 30 to go into his hospital. He gives out that the K. pox will preserve from infection for a few months *but no longer*. Lest this insidious conduct should make a gap in our inoculation, and lest that should break the continuity of the matter, I have to request you earnestly to send me some more vaccine matter by the Galen and the Minerva, or any, or every opportunity. No one in this quarter is now inoculating but myself, and I fear lest being thus alone I should be divested of the virus. Of all modes, I prefer that on cotton thread, well and repeatedly soaked in the 8th day virus. Mr. Wachsal sometimes sends it from cases on the 10th, 12th and 13th days, but I am doubtful of all taken after the efflorescence has formed. I pin my faith on Jenner and his rules. He is *my* polar star. He is the only unconfused writer I have yet met with on the Variola vaccinae.

The circle of your friends is, I believe, as entire as when you left us. Our season has been fine, and it is not unhealthy. The malignant fever (probably yellow fever, WCA) has again appeared at N. York and in Maryland, but milder and later in the season. Did you see Dr. Haygarth at Bath? If so, did you get introduced to him personally?

Capt. Barrow paid half of his note. J. Bartlett, the whole of his. Scales, nothing. Mrs. Waterhouse is obliged to pester you with a little frivolous commission. To procure for her at what is called a Turnbridge-ware house, or Turner's shop in London four setts of *Butter stamps* with rims, to them. They are for the purpose of making the round stamps of butter for the breakfast table, being such as Major Brattle used to have at his table. Each sett may cost a shilling or eighteen pence. She wishes to have the four setts of four different sizes. As to the figure of the stamps, be sure to get the *prettiest*. This turned work is made at Tunbridge and sold in every street in London. Mrs. W. and the children desire their best regards; so do my mother and sister; and so do Mr. and Mrs. Mellen, and the young ladies. Did you ever hear Mr. Mawman say anything of a manuscript he is about publishing of mine? Has Dr. Lettson published his Eulogy on the Cow-pox? Anything you wish to send

will be taken good care of by Capt. Hinkley of the Galen or Capt. Barber of the Minerva. The stamps may be sent by either; but if you wish to send a single letter, or indeed a packet, you have only to get some acquaintance to transmit it to Liverpool, where there is almost always a ship up for Boston. Not a week but that you may send that way. I will send a few of my pamphlets to Dr. Jenner by the Galen or Minerva. They sail in ten days.

BENJAMIN WATERHOUSE."

"Cambridge, April 15, 1802.

Dear Sir:

I received your letter of Feb. 2nd with great satisfaction, and lest you should not receive from your relations any letter, I thought you would not '*begrudge*' a shilling to have a letter via Liverpool, if it announced the continued welfare of your friends and relations. I saw Mr. Packard lately and also Gen'l Bridge, and have had several kind enquiries after you from Deacon Morris.

You mentioned having sent me some vaccine matter by the Galen, but I could find no letter or packet on board her. She brought me no letter from any of my London correspondents, which was rather a disappointment. By the Minerva I received one from Dr. Jenner, and have in return sent him an account³ of the diffusion of the blessings of his discovery among the tribes of Indians by the immediate agency of President Jefferson.

A grand embassy of warriors were at Washington last winter when the President explained to them the precious donation which the great spirit had lately made the enlightened white man. He then caused all the warriors to be inoculated for the Kine pox and when they departed had the *matter*, with an abstract of the directions I had given to him, put into the hands of the interpreter, and told them that they would not only be secured by it from the S. pox, but that it would finally extirpate that disease from the earth. I have sent the anecdote to Dr. Jenner, and which I hope will reach Mr. Ring. I am inexpressibly disappointed in not receiving a continuation of his treatise. I wish to see it before I publish mine.

The measles are diffused through the whole country and I fear that we shall all lose our vaccine matter by it, because, some are under it, some just got over it and others expecting of it. On that account I have to request my friends in London to favor us with some of the virus by the different ships. I am indeed very apprehensive that we shall lose the matter from that cause. I hope Mr. R. will not name Aspinwall in terms that may hurt his feelings. I have many apologies to make for him. There are hundreds worse than he is in the opposition. His hospital is his own property and he will lose 1500 guineas a year by it.

Mrs. W. thanks you very cordially for the butter stamps. You have done so well in it that she is encouraged to employ you again. She wishes for three or four of 4 inches diameter, that is 2 circular ones—and 2 oval ones, or as she expresses it stamps that will hold a $\frac{1}{4}$ lb. of butter. Those you have sent are very pretty and much admired. Are there any stamped with the spread eagle of America? Make a minute of these little expenses for me in your pocket book. The children desire their love to you. John made him a long lash whip the other day and I overheard him say in the intervals of snapping it, 'I will write down the day of the month and hour when I snap'd it, and ask Mr. Spalding if he did not hear it crack all the way to London!' Daniel says you must send him a young elephant, Benjamin wants one of the lions out of the tower, or if you can't easily get one of them you may send him, he says, a crocodile.

Adieu, your friend,

BENJAMIN WATERHOUSE.

P. S.—Geo. Stroud has a majority of votes over Gerry of *ten thousand*. I am glad to hear by you that Mr. Mawman is about putting my manuscript to press. By this opportunity I have sent a letter or dissertation on Natl. History, or rather a *sketch of my course of lectures* to be inserted in that volume. I would thank you on receipt of this to say as much to Mr. M. without saying that I desired you to, for I have addressed the letter to Dr. Lettson who may thro hurry of business omit to

¹ This playful passage is explained in a letter from Waterhouse to Jenner, to be found in the former's tract on vaccination published in 1810, p. 52. He wanted material for a short sketch of Jenner's life.

² Aspinwall ran a smallpox inoculation hospital in Boston, and naturally faced ruin if vaccination should prevail. In the next letter we see how charitable Waterhouse was towards him in the matter. Jenner had exactly similar difficulties with Woodville, the head of the smallpox hospital in London.

³ An almost identical account of this event is to be found in a letter Waterhouse wrote Jenner, April 8, 1802 (Baron, 1888, 1, p. 593).

attend to it. It is additions, etc., to what I wrote four years ago.

If you understand me, my meaning is this, I wish you to mention to Mr. M. in a casual way that you find by a letter from me that I have sent an additional letter for that work in which case he will enquire for it of Dr. L., should Dr. L. through hurry, have neglected it."

The following letter from Jenner to Spalding explains itself. As I have said before, it deals with one of the earliest shipments of vaccine to America:

"Dear Sir:

From the time I rec'd your communication relative to the sailing of the ship to America, to the present hour, I have met with such incessant interruptions that I c'd not get my parcel ready for Dr. Waterhouse till now.

I have written a long letter, or rather a long incongruous scrawl—the Dr. perhaps little knows the harassing kind of life I lead here—I wish you w'd in some measure explain it to him that it may prove an apology for my incoherent letter. I have sent some Vac. matter to the Dr. Perhaps you made the request for yourself. If so, pray let me know it.

Yours very faithfully,

E. JENNER.

Tuesday night."

The pressure under which Jenner carried on his correspondence is well shown in another letter of his to Waterhouse, which is published in the latter's "Information, etc." (Cambridge, 1810, p. 52). There he says: "And now, my good doctor, I would fain proceed further and double my epistolary account with you; but our friend Spalding tells me that if I do not make haste, the ship intended to convey this will be gone. I have not said half I wish to say—but I am at this moment fifty letters behind-hand with my correspondence—a distressing idea." If only he could have had a stenographer and a typewriter!

We know from Baron (p. 386) that this correspondence between Waterhouse and Jenner was kept up with increasing interest and attachment until nearly the close of Jenner's life. Such friendships between scientific workers who have never met are beautiful and, I believe, represent humanity at its best.

177 Post Street.

Why Worry?—"Worry," says Herman N. Bundesen, "is a waste of time and energy, accomplishes nothing, and gets nowhere. Worry creates a surly temper and an habitual grouch. It puts a damper upon ambition and is a wet blanket upon happiness. It's a 'joy-killer.' Worry gives a jaundiced look on things, disturbs mental balance, and lowers resistance to disease. The life of the worrier is just what he makes it—an unbalanced existence. The remedy for worry is cheerfulness, and this is to be found in planning good things for the future, living more contentedly in the present and not at all in the past, having more faith in God, talking less, listening more, keeping occupied, and cultivating optimism. Look at the doughnut, not the hole."

Reorganization Meeting of the State Medical Society of California, October 19, 1870—It was for such purposes this society was formed: To bring the members into harmonious unity of action; to cause mind to bear on mind; to work out the problem of climatic influences on the physical condition of man; to investigate the nature and causes of endemics and epidemics; to determine the best methods of holding life and health in integrity, and to remedy the evils incident to existence—these I conceive to be its prominent aims. (From Address of Welcome delivered by Thomas M. Logan.)

SOME HISTORICAL INCIDENTS IN THE DEVELOPMENT OF THE OPERATION FOR CATARACT

By HANS BARKAN, *San Francisco*

IN OUR attempt to describe and bring forth the relation to each other of the main developments of the operation for cataract, we find that we are asked to include a period of two thousand and more years. The development of the operation to its present very nearly perfect state was dependent upon the natural development of knowledge during the course of this period, partly upon the development of certain specialized forms of learning, and partly upon emancipation from prejudice and bigotry.

The literature on the subject is immense, though comparatively little is extant in the *original* Latin or Greek. These writings disappeared long before the time of the Arabians. With the pillage and sacking of cities and the destruction of their libraries, many of the original descriptions of the operation vanished, and it is mainly through the translations into the Arabian that we are still able to obtain very nearly first-hand knowledge of what the ideas of the Romans and Greeks were.

In our appreciation of operating methods and of general knowledge appertaining to cataract among the Greeks and Romans, we must not forget that translations into the Arabian were not always accurate and were often not from the original Latin, but from various forms of degenerate and colloquial Latin. Furthermore, that the Arabians interpolated their own conceptions of what the original Roman or Greek surgeon may have meant, and that often an Arabian word meaning one thing may have had in the Latin original one of several meanings, and vice versa, so that the translations which we possess of the Arabian manuscripts, English, French or German, give in many cases a different meaning from that which the original Latin or Greek description meant to convey.

A case in point is the question as to whether the Greeks and Romans ever suspected the true nature of cataract. What did they mean by the removal of a cataract? Was not to them any obstruction to sight that was visible within the anterior chamber or within the pupil a cataract? Did they not include hypopion and secondary pupillary membrane? We wonder whether some of the very earliest accounts of the actual removal of the lens from the eye do not refer to an incision into the cornea for removal of a hypopion.

Galen says: "The cataract is brought to another location where it disturbs less, but a few have attempted to empty it entirely." The original of this work is lost, as is the work of Antyllos, which Razi has preserved for us in Arabian and in which it is stated, "I have split the lower part of the pupil and have led the cataract outward. This is possible with the thin cataract, but with the thick it is not possible because the egg jelly moisture would flow out with the cataract."

Hirshberg, who has gone most carefully over the Arabian text, with which language he was familiar, doubts that the leading out or pulling out of the cataract is the sense of the word, but that it is more

apt to be one meaning "pasting it down," and would therefore refer to some method of couching.

We are not in a position to state what may not have been done occasionally and what may not have been done in times long before there exist any records. Celsus, a contemporary of Christ, gave the earliest description of cataract operation, viz., that of couching. Three centuries before the dawn of the Christian era there is historical mention of ophthalmic surgeons in Alexandria, and Galen states that some of these surgeons devoted themselves exclusively to operating on cataracts. Celsus speaks of the writings of a famous Alexandrian surgeon named Philoxenes, who lived 270 B. C.

We have proof, then, of some form of cataract extraction as long as two thousand years ago. That, except for occasional isolated instances, the operation in the main remained the same for many centuries is scarcely to be wondered at. It remained the same in principle in the hands of the Greeks, the Romans and Arabians, and later in those of the surgeons of the Dark Ages of Central Europe.

The knowledge of anatomy of the eye was a most rudimentary one through all this period. No surgeon had any real conception of the nature of cataract, or that the crystalline lens was displaced by the operation. It was held to be an effusion from either the posterior or the anterior liquids of the eye. The rough drawings of ocular anatomy show an entirely erroneous idea of these chambers and of their sizes; the humoral pathology of the time led naturally to the conception of effusion.

So matters stood until Brisseau's discovery of the real nature of cataract, and of Daviel's delivery of the lens through a corneal section, not two hundred years ago. From that time on to the present, the great advances in surgery of cataract have occurred—advances associated with the names of Daviel, Brisseau, Heister, Mery, Maitre-Jean, Morgagni, James Ware, Wenzel, von Graefe, Beer, Wecker, Schweiggert, Arlt, La Faye (the originator of the intra-capsular operation), Richter, Mackenzie, Rosas, des Marres, Pagenstecher, Knapp, Smith, Barraquer and many others.

The technical development of the operation since the days of Daviel has been great; the eminently satisfactory results of today, however, not attainable until cocaine and asepsis had made possible the painless and cleanly performance of the technical improvements.

Let us in the main interest you in three great periods. The first, that of the Arabian methods and schooling; the second, that of the operation as carried on during the Dark Ages in Central Europe; and the next, the epoch-making work of Daviel.

Civilization following the period of "the glory that was Greece and the grandeur that was Rome" had its throne in the East. Bagdad was not only the political capital of a far-reaching empire, but the focus also of all scientific endeavors. There were read with enthusiasm Aristotle and Plato; there the scientific world gathered and there mathematics, and astronomy based on Euclid, were called into life.

Based on Hippocrates and Galen, medicine was advanced and an endeavor made to investigate the secrets of nature. The treasures of the Arabian world in contrast to the poverty of Christian Europe

of the Middle Ages is hard to imagine. The geographer Jaqut in 1200 A. D. found in a small Arabian city twelve libraries, each of 12,000 volumes. Bagdad, a short time before its destruction by the Mongolians, contained not less than thirty-six libraries; the library of its ruler in the ninth century contained 80,000 volumes; that in Cairo, 2,000,000 volumes; that in Cordova, 600,000 volumes. Arabic was the world language. In this language, then, we find the translations of Greek and Roman medicine, and a number of their own medical works, the most famous one perhaps being that of Razi, which kept

Jacques Daviel

its place throughout the Middle Ages and into the seventeenth century, being used as the foundation-stone of many of the university lectures in medicine, in Central Europe.

Abul-Hasan, Ali B. Al-Abbas and Ibn Sina are famous names, the latter more familiar to us as the Avicenna of the Latin translations of the Middle Ages. In their writings are to be found many trenchant observations; many of the drugs used today were familiar to them, and their ophthalmological knowledge especially was saner and freer from absurd and filthy methods of treatment than that of their successors.

The Arabians as far as cataract was concerned, did not, however, in spite of their incisive power of observation and deduction, go further than crude methods of relieving blindness. The couching of cataract by means of various shaped needles was the standard method of procedure. Some of their ideas regarding the circumstances favorable for the operation and the method of performing it are interesting.

So says the Persian, Abu Ruh Muh: "Should

someone ask you how one couch the cataract, and how many varieties of doing this there are, so answer, 'One operates the cataract in three methods: first, with a little knife or a needle; second, with a solid lance, and third with a hollow needle.'

Antyllos and Paulos describe it somewhat as follows: "In performing the operation put the patient in the shadow opposite to the sun ball; his head be held tightly; he look toward his nose without deviating from this position. Now let the surgeon put his instrument as far away on the temporal side of the cornea as is the distance between that and the pupil. Let the surgeon take the tail of the needle and press it into the eye so that a mark is left, and taking this spot let him shove inward and forward the needle. Wind a thread about the needle so that it do not penetrate too deeply. Is now the needle in the eye; bring your mouth close to the eye and blow upon the same so that the pupil remain undisturbed. Now press downward, and press the cataract toward the lower part of the eye. Should the cataract be a difficult one and return into place, break it up toward the sides where it seems to you easily disposed of until the patient sees immediately. If this has succeeded, draw out the needle and lay upon the eye egg albumen with rose oil for three days. Lay the patient then upon his back, rub some white salve on his eyes, for they must hurt him. Should only one eye be operated upon, the other one, however, must be bandaged with it. So let him lie and sleep upon his back in a dark room, and be visited frequently and regularly that one knows exactly his condition. Let him beware of singing, talking and coughing. Do not change his bandage for three days if there be no necessity."

The demands upon the operator were: "The cataract operator be of good vision, of a clear, penetrating gaze, of sharp sight, possessed of knowledge of the interior of the eye and of the optics of sight. Let not his hand tremble; let him step toward the eye with courage; let him be fearless when pressing in the needle, and free of dizziness. Let him not be ravenous for operations, and let him choose the best times."

To be ambidextrous was demanded on the part of all the Arabian authors. We know today how valuable an attribute of the cataract surgeon this is. The influence of the seasons and of the time of day were held to be of great importance. A sunny day between autumn and spring was preferred. Says Hippocrates, as quoted by the Arabians: "Let the surgeon wait for twenty days after the mid-point of summer, autumn, winter and spring, during which time the patient should be regular in his diet, and freely move his bowels." Says Ali Ben Isa: "Let the day be one of the northerly sun, not of the southern one. Let him sit opposite to the sun on a cloudless day, and not a day when the sun is not north." Evidently he means a clear, sunny day in time interval between spring and autumn.

The most courageous and best of the cataract operators of the Arabians, Ammar, however, values the time of the year and the state of the weather so little that he does not even mention it.

As regards position, says Ali Ben Isa: "Let the patient sit upon a soft pillow and tie his knees together and against his breast, and also his hands one

against the other and against his thighs. You, however, sit upon a stool so that you are somewhat higher than the patient's head. Bandage the eye that you are not operating."

Says Ammar: "Sit the patient before you, but you so sit so that the head of the patient is opposite your breast. Then command the patient to fold his hands about his knees. If the cataract be double-sided, bandage the left eye." In order to be positive that the cataract rise not again (the dread of the operator), Ammar commands the patient "to cough, to snort, to grind one row of teeth upon the other," all this with the needle still in the eye in order to make sure that the cataract will not rise afterwards. The after-care was done with great precision. On the fourth day the patient was allowed to sit up, but had to be very careful until the seventh. He must avoid chewing and drink little water. He must lie in a dark room as if dead. Ammar changed his bandage every day. On the fourteenth day the patient could take a bath, and after that do as he pleased.

Salah Ad Din adds the following useful precautions: "One should avoid screaming and threshing of wheat in the neighborhood and evil smells and things which cause sneezing. Let his couch be free of fleas and from everything that might disquiet him; nourish him with dates and sour cream; wash his eyes with woman's milk and lay upon them the yellow of egg and oil."

Perhaps we have gone far enough in presenting this picture of the Arabian cataract conception. We see, in striking contrast to the charlatan and degraded practitioner of the Dark Ages of Europe, a group of really eminent, thoughtful and sincere men who had the insight to obey some natural causes, and had an amount of sympathy for their patient's welfare and precautions for his recovery that illustrate the noble and humane sides of the Arabian character.

The couching methods of their time are still carried on today in perhaps even a cruder way by the couchers of India.

The interesting volume of R. H. Elliott on the Indian operation of couching for cataract describes the present day methods: "Their methods are dirty, septic to a degree. Their surgical equipment is carried in a bag or in a box which would be considered dirty alongside of a tool chest or work basket of any English artisan. The filth alike of their clothes, their hands and their person staggers description from a surgeon's point of view." Some of their tricks are quite similar to those employed by the cataract operator of the Dark Ages of Central Europe. The Indian charlatan of today has tricks that even his predecessor of the Dark Ages was not aware of."

Elliott relates the following: "The operator and his assistant took the patient alone into a darkened room; a candle was lighted and kept carefully behind the victim's back by one of the rascals, while the other in front asked if he could see the flame. A sham operation was then performed and the process was again repeated, but this time in front. Naturally the blind man could now see the light and, on being assured that the change was due to what had been done, his gratitude was likely to rise to the production of the necessary fee. If it did so,

the impostor speedily made off. It seems hard to believe that even the Dark Ages were dark enough for so transparent a trick to be tried often in one town." "In India today the patient and operator sit facing each other in a good light. Both squat on their hams in accordance with the immemorial custom of the East. The patient is frequently, if not usually, told that no operation is to be performed; that it is merely a question of putting medicine into the eye. He is requested to look downward, and the coucher raises the upper lid with one hand, whilst in the other he conceals a needle or a sharp thorn; it is said that the needle-like thorn of the babul tree is usually selected for the purpose. In the majority of cases at least it would appear that no form of local anesthesia is attempted. The needle or thorn is thrust suddenly through the cornea and on through pupil or iris into or on to the periphery of the lens. The next movement, which appears to follow the first so rapidly as practically to merge into it, is that of depression or reclinatation. In nearly every case the operator tests his patient's vision immediately after the operation by holding up fingers, colored cloths, necklaces or other common objects for triumphant identification. The eye is bandaged for at least twenty-four hours. By the end of that time the operator has frequently placed a safe distance between himself and his patients of the day before, and is seeking fresh dupes in another village."

I have brought out these points of the present-day couching operation in India in order to come back to the couchers of the Dark Ages. They traveled with their needle concealed in their broad-brimmed hats or sleeves, and many of them were preceded by a "ballyhoo" artist who, for the week previous to the arrival of the famous doctor, sang his praises in the community about to be visited. Small stages were erected in the center of the mediaeval town square upon which entertainment and sleight-of-hand tricks were performed. Occasionally the charlatan's advance agent consisted of accomplices who praised from the public platform the great man about to come, and declared that they had been blind, and lo! they could now behold the eye of a needle.

The blind came from near and far on the day of the surgical carnival, for not only cataracts but every other blind were relieved of their difficulties. It is true that the operator, as does his modern Indian cousin, did not seek a permanent residence in the town of his activities; but bandaging his patients' eyes for seven days with strict injunctions not to remove the bandage before the time, and being possessed probably of as lively heels as he was of nimble wits, laid a safe distance between himself and his victims.

It is among gentry of this ilk that the famous Dr. Eysenbarth of the sixteenth century belonged, of whom the verse is still sung in Germany:

Ich bin der Doctor Eysenbarth,
Curier die leut nach meiner Art,
Kann machen das die Blinden gehen,
Und das die Lahmen wieder sehen.

Far from the position of dignity which the ophthalmologist among the Arabians enjoys, the ophthalmologist of the Middle Ages sinks to the level of the clever clown and is not held in any esteem by the decent men of his times. They kept whatever

secrets of success they may have possessed either to themselves or offered it for large sums to those who would spend sufficient time as their assistants. They continued the operation in about the form that had existed for hundreds of years, though there were exceptions to which I will come.

Richard Banister in 1622, translating in the main the work of Guillemeau, offers the following poetic views which incline one to believe that he was perhaps not related to the average quack of his times. To comfort the patient he says:

"Like cloudy vapors
See the eyes o'ercast,
Yet vanquished as the dew
By the sun at last."

And again:

"Our practiced, careful skill, with observation,
Will teach the mystery of the operation;
To end this work, that perfect it may stand,
God guide with perfect skill, our eye, our heart, our hand."

And once more, the fit time for couching the cataract:

"Couch cataracts upon a day so fair
That neither wind nor clouds disturb the air;
When spring with simples fills the earth's rich lap,
Or autumn makes the tree put off his cap,
The moon is full, or in conjunction sly,
Or tracing Aries or in Gemini."

The Englishman Banister is the counterpart of the German Bartisch in his superstition, professional narrowness, and envy of his competitors; also in the cleverness of his manual work, in his honesty, in the faithfulness of his presentation and his gift for poetry. Bartisch, whose activities were in the middle of the sixteenth century, has written a book of ophthalmology which gives him the position in ophthalmology of those times that the shoemaker Hans Sachs of Nuremberg held in poetry, or the shoemaker Jacob Bolme in philosophy. At the age of 13 he was apprenticed to a barber and a surgeon; in the year 1588 he was court ophthalmologist, not, however, before the city of Freiberg in Saxony had found it necessary to proclaim that "the eye doctors George Bartisch and Simon Hoffman shall stay at the saddlers' corner in the neighborhood of the market; the other noise-makers, however, shall remain in the middle of the square."

Be this as it may, he was an honest man, and his book, a copy of which is in Lane Medical Library of Stanford University, is well worth study and of great interest. His book is one of the very first complete presentations, *well illustrated*, of ocular surgery.

In this state of chaos, superstition, and lack of knowledge of what a cataract really was, we leave the Dark Ages to find that, as in all other branches of science, knowledge of the fundamentals was necessary before any progress could be made.

The first who demonstrated that the anatomic position of a cataract was in the lens was the famous anatomist of Jena, Werner Rolfinck, who established this fact in 1656. With more generosity than is sometimes found in modern days, he expressly states that he has only confirmed the teaching of Quarre, the Parisian physician and surgeon; and on two occasions has demonstrated the lens to be the seat of

cataract through the anatomical examination of the dissected eye of the dead.

Before him Plempius, in 1632, had spoken of this theoretical possibility, as had the Arabian Arculanus in 1420. As in all development of really proven facts which from this time on occur in rapid strides, the question of priority arises. Men before the days of Rolfinck, Quarre, Brisseau and Daviel had mentioned theoretical possibilities, or had even occasionally stated that they had done this or that; but it is only with these men that the facts were firmly founded, and to them belongs the credit.

Others, such as Borel and Gassendi, maintained that cataract was the opaque lens, but they could not

with this fact established, the first start toward a rational conception of cataract surgery was begun. It is interesting as pointing the way in which discoveries of such magnitude sometimes originate to see in what fashion Brisseau was led to his discovery. Says he:

"Nothing was further from my mind than the examination regarding the character of a cataract. I happened to hear that a thief who, in order to disguise his business, had been giving himself out as an *oculist*! was to be executed, and I wished to obtain the cataract needles in his possession which happened to be missing from my instrument case. In obtaining these I was reminded of some doubts which I had entertained previously in regard to the character of a cataract. I made several trials on the eyes of animals and found that I could not advance my needle according to directions from behind forward into the water of the chamber without boring through the lens. This, according to previous ideas, must have destroyed vision, for the current belief was that the crystalline lens was an object absolutely necessary for vision. I awaited my opportunity, which came in the form of a soldier who, possessed of a cataract, died in a hospital. After his death I performed the operation upon his eye. I then dissected his eye and found the lens opaque and hard and pillowed in the vitreous where I had sunk it, and so came to the conviction that the genuine cataract is in no case a skin or effusion produced by the fluids of the eye, but is a hardening and opaqueness of the crystalline lens."

Boerhaave, Morgagni, and Valsalva all supported Brisseau, and the acceptance of the real structure of cataract was soon firmly established. In our day we can scarcely appreciate the psychology of those times, the pertinacity with which the scientific world clung to the revered teachings of Hippocrates, Galen, and Celsus. As little as new ideas in theology met with favor, did scientific truths that were in opposition to the gospel of the old scientific testaments. The establishment of a truth of this sort formed the greatest milestone in the development of the cataract operation of today.

It is noteworthy that in France particularly these new adventurers in the scientific reconstruction of surgery and anatomy flourished, and that only in a later period, after the fall of France as the leading world power, did the German school of great progress in surgical development take place.

As the undisputed leader in the surgical development of the cataract operation of today, we find Jacques Daviel. Daviel had been immediately preceded by operators of great experience and brilliance, such as Charles Saint-Yves, who in thirty years yearly performed eighty to one hundred couchings; the surgeon d'Aigaillon of Orleans, who in thirty years was supposed to have had two thousand successes in the operation of couching; Master Antoine, and the Englishman Woolhouse, who in 1717, after practicing for twenty years in Paris, boasted of several thousand cataract operations.

We find with Daviel's time the foundation of the charity hospital in Berlin in 1724, and in 1732, the Academy of Surgery founded in Paris, whose fate it was to hear Daviel and to judge of his claims as

Mr. A. von Graefe

make a breach into the wall of Galen. It required a more violent attack and a more passionate battle to destroy these old teachings, and this hero and victor was the young French physician, Michael Brisseau.

Brisseau maintained in many theses, in correspondence and in popular discussion, that a cataract was nothing but the opaque lens, and the matter was so thoroughly aired and discussed that from then on it was taken as an accepted fact.

Maitre-Jan shares perhaps with Brisseau the credit. He noticed in 1682, in depressing a cataract which appeared in the anterior chamber, that it was not a thin skin or effusion, but a round, thick, white body. He opened the eye of a cataract patient after death and found that the cataract was opaque lens. He performed an examination of the eye that he had operated on after the death of a patient from pneumonia and found the same to be true.

The presentation that he and Brisseau made before the Parisian Academy settled that matter, and

to his new operation. Here, too, the first course of instruction in diseases of the eye and their treatment, held under the auspices of a recognized institution, was given by de la Martiniere, and finally, the foundation of the College of Surgeons in London in 1745.

Two thousand years nearly had passed since the first record of cataract operation. With Daviel we come to a period in which, following knowledge of its anatomic position, ways and methods have been contrived within the last two hundred years whereby we have proceeded to a radical expression or extraction of the lens. Two thousand years of couching became history.

Preceding Daviel, this possibility had been mentioned by Steven Blankaart, but it was left to Saint-Yves and Petit to remove a dislocated lens which, after couching, had dropped into the anterior chamber. They inserted a needle into the cataract and removed it by a short incision through the lower portion of the cornea.

The famous Baron Taylor boasted that he had, in 1737, removed in England, by means of a corneal incision, various cataracts which were behind the iris, but he was disbelieved by several of his contemporaries, and Hope, his countryman, declared, in 1752, that he had seen Taylor operate for six months in Edinburgh and depress several hundred cataracts, but had not seen him remove one from the inside of the eye a single time.

Taylor was undoubtedly a genius; a man as vain and boastful as he was able, and as fluent a liar as he was an operator. His greed for praise and money, and yet the undoubted genius of the man, made him at the time one of the figures of ophthalmology.

The more we read of the predecessors of Daviel the more we come to the conviction that in him is found the first figure both upright, clear-sighted, energetic, brave, persistent and scientific, and that he well deserves to have us feel that he is present in spirit at every cataract extraction, a house god in the home of the ophthalmologist.

He was the son of people of humble station in life, industrious and loyal to their king and to their church. He was born at the close of a century that had been made memorable, not only for what the grand monarch of the age, Louis XIV, with his grand cardinals, had achieved in conquest, in authority, in social display, in religious supremacy, but for what had been accomplished in the advancement of literature, art and science. Painting, sculpture and architecture were in bloom, institutions of learning founded and encouraged, science promoted.

His early life remains in great obscurity. In 1730, at the age of 20, he was attached to the army as student surgeon and served in the army hospitals. When the plague broke out in southern France he was commissioned to go to the relief of the plague-stricken population. In the midst of the plague he married, and on the fifteenth day after his marriage Daviel and his young wife departed for Marseilles, where he again devoted himself completely to the care of the plague-stricken.

Due to his work there he was admitted to the Corporation of Master Surgeons without examination, and was later one of the surgeons at the City Hospital. There had never been official teaching of

anatomy and surgery in the hospitals, and Daviel worked and sacrificed in order that this be made possible. He was given unusual privileges in regard to cadavers and became an enthusiastic student and teacher of anatomy.

It was at this period that he performed his first operation for cataract, using the method of depression which was the only one then known. He immediately became intensely interested in the surgery of the eye, acquiring much skill as a surgeon-oculist, and soon became so skilful that, after having been called to several large cities to operate upon cataract, he came to the great medical center of Paris at the age of 53 in 1746.

Daviel brought depression to a more exact point by devising new instruments and by continuing to make experiments daily on the eyes of cadavers. He was first led to be enthusiastic about the possibility of removing the lens from the eye by having failed to depress a cataract. Failing, he decided to open the lower part of the cornea, and the exact manner he does not describe. After making the opening he held it apart by lifting the corneal flap with small forceps and, introducing a needle into the posterior chamber of the eye, the lens was brought out, followed by a small portion of vitreous body. The eye regained its natural form and saw well. The result was so successful that it gave him, as he says in a letter, "great ideas in regard to the extraction of cataract."

Finally he performed his first predetermined, pre-arranged extraction. The case was that of a woman whose name, age and condition he does not give. He opened the cornea with a small knife, then enlarged the incision with small curved scissors. He then passed a small spatula to the upper part of the cataract and "detached" it, and with the instrument drew it out in small pieces. The pupil appeared clear; there was not the slightest accident, and in fifteen days the patient was well.

Further successes gave him more and more assurance, and finally, in 1750, he had had sufficient experience to cause him to resolve not to operate except by extraction.

The operation which he had invented and now made public consisted in incising the lower part of the cornea and extracting at its junction with the sclera. He first made an opening into the anterior chamber at the extreme lower margin of the cornea with a triangular-shaped knife and then after withdrawing this he enlarged the incision on both sides with a narrow, blunt-pointed double-edged knife as far as he could easily, and finally, when the cornea became too much relaxed to continue the incision, he completed it to the extent desired with delicate scissors which were so curved on the flattened end as to correspond to the curve of the cornea-scleral line. These, of course, were made right and left, the blade introduced into the anterior chamber being blunt-pointed. Having completed the incision, he lifted up the corneal flap with a small spatula and incised the anterior capsule of the lens with a sharp-edged needle. After doing this he carried the spatula between the lens and the iris and delivered the cataract by pressure from above.

Various modifications in the shape of triangular flaps of the cornea were tried by him. In a letter

addressed to the *Journal des Savants* in 1756 he said: "I think no one doubts the excellence of so good a method, for out of 354 persons that I have operated on, 305 were perfectly successful."

Again, in a letter of 1756, he stated that he had, during the preceding sixteen months, extracted eighty cataracts, with only one failure. Even granting that the standard of success was not as high in regard to vision and other desirable factors as today, we must regard these statistics as astonishing. He continued his beneficent work for years, and was called to all parts of Europe to operate.

It was his fortune to be recognized during his lifetime, and to be elected to membership in nearly all

in all its prime essentials. Such an operation is still used by most of us.

It would carry us too far and come too close to modern days and our immediate knowledge of modern surgery to enter into any description of the historical aspects of the times since Daviel. The great von Graefe stands alone in his genial experiments with the size and location of the incision, and with his never-failing efforts to obviate the difficulties of the healing of the wound which originally led him to perform iredelectomy, believing that this obviated infections and trauma to the tissues in the expression of the cataract. His description of his reasons for iredelectomy in cataract extraction and his method are well worth reading in the original, appearing in the *Archives of Ophthalmology* in the year 1859.

The names of many great men—Beer, Jager, Arlt, Sichel, des Marres, de Wecker, Scarpa, Potts, and Langenbeck—fall between the periods of Daviel and von Graefe. Some of them had improved methods or improved instruments; others, such as Potts and Langenbeck, actually strove to turn back the hands of the clock and advocated passionately recination and kerato-nyxis.

To the Austrian school of Beer, Jager, Rosas, and Arlt belongs finally the great credit of having formally established the extraction of the cataract in opposition to the reversal to antiquated methods which threatened to nullify Daviel's efforts.

The extractions of today are well known to us all. The extraction in capsule by Smith's method, or by Barraquer's; the lifting out of the lens by appropriately shaped forceps; the various modifications of conjunctival flaps and safety sutures—all these will in time form a historical study for the generation of ophthalmologists hundreds, perhaps thousands, of years from now.

Perhaps, if summed up, the high lights in the operation of cataract might be said to be the work and methods of the Arabians; the work of Brisseau and Daviel; the work of the Viennese school, and the work of von Graefe.

It was Anatole France who, on being reproached by a friend that his library contained only the works of the ancients, and that he paid scant courtesy to his colleagues by not including theirs, said:

"I know what *they* think. What I want to know is what those *before* me thought, and I would like to know what those after me will think."

516 Sutter Street.

Cataract operation of the 17th Century

the scientific bodies and academies of Europe. His death occurred in Geneva, probably due to cancer of the larynx. His grave there is surmounted by a monument erected to his honor by Swiss oculists.

His operation has been changed, in regard to the location of the incision, and has been changed in regard to the use of a single knife instead of the multiplicity of instruments. The problems dealing with the complications of extraction have been met and worked out during the 172 years since his time. The names and work of the many eminent men since that day form the concluding chapter toward the perfection of the operation.

The operation has been the subject of the closest attention and study, and has encountered an infinite number of modifications. And yet today, substituting for Daviel's knife and scissors the modified knife of Tenon of 1757, as represented in the von Graefe knife, making the incision upward, not downward, adding in appropriate cases the iredelectomy of von Graefe, we have still the classic operation of Daviel

Prevention as the Primary Duty of Physicians was Old Then as Now—It has become the imperative duty of every physician to be a preacher of the gospel of life and health, if he has any exalted appreciation of the aims and ends of his calling; and inasmuch as in the science of health there are more exact demonstrative truths than in the science of disease, so that duty demands, as it richly deserves, an unbounded share of our professional energy. As teachers in this nobler work of *prevention rather than cure*, we must not only show mankind what the laws of nature are, but how important is a strict adherence to them; in other words, we must, by every means in our power, by example as well as by precept, strive to advance them in the scale of intelligent beings. (From President T. M. Logan's Address at the First Annual Meeting of the Medical Society of the State of California, October 11, 1871.)

THE CALIFORNIA PANDEMIC OF 1833

By EDWARD W. TWITCHELL, M. D., *San Francisco*

THE population of California in the early part of the last century has been variously estimated. It consisted of the dwellers in and about the chain of missions and presidios extending northward from San Diego, a Russian colony or two north of San Francisco Bay, and scattered pioneer holdings here and there, forming the civilized element, and a great number of Indian tribes spread out over the whole country from the coast to the Sierras. The numbers in the missions were pretty exactly known, but of the great population beyond the missions only estimates could be made, and these were naturally only approximations.

When La Pérouse, the great French navigator, left Brest in 1785 with his two frigates on the voyage that ended so disastrously, he went first toward the North Pacific, reaching this coast in 1786. He estimated the total population as 50,000, of which 10,000 were neophytes attached to the missions. Vancouver, in 1793, thought there were 20,000 neophytes and eight to ten times as many in the tribes. An apparently official census of the missions only in 1795 showed 12,216 in the missions. A similar census in 1805 showed 22,637. The Mexican census of 1831 estimated 27,000 Indians in the state, but this was so far from the estimate of other observers that it should not be considered.

Hittel, whose estimate is among the lowest, says that 50,000 Indians were probably the limit. Most observers who really traveled through the interior of the state agree that the Indian population was very numerous.

Colonel Warner, speaking of a trip made through the central valleys in 1832, says: "On no part of the continent over which I had been or have since traveled was so numerous an Indian population as in the villages of the Sacramento and San Joaquin Rivers."

According to Bancroft, the Indians north of San Francisco were more numerous and warlike than the others. This refers apparently to the coast counties.

C. Hart Merriam, in a recent paper on the Indian population of California, places it at 260,000 at the time of discovery, reduced to 210,000 by 1834, and again to 100,000 by 1849. In 1920 it was 17,360 by Federal census. The greatest number in any one county is 1958 in Riverside, due to the presence there of an Indian school. Humboldt, with 1829, has the largest number living under what are approximately natural conditions. The recent estimate of Merriam's is very close to that of Vancouver in 1793.

There was good reason for a large population, as de Mofras says in 1841, "*Le Rio del Sacramento coule dans la plus magnifique plaine que l'on puisse imaginer . . . le seul animal à craindre est l'ours gris.*" Vol. I, p. 454. The rivers were full of salmon and other fish. Life was easy and there were means of support for a great number of people. But what a people! Vancouver says: "If we except the inhabitants of Terra del Fuego and Van Dieman's land, they are certainly a race of the most miser-

able beings I ever saw." At another place he gives a very moving description of the filth in a hut which he inspected near Monterey. Hittel says he calls them "horrid," but I failed to find this.

You no doubt recall Mark Twain's reference to "those degraded savages who roast their dead relatives and then mix the human grease and ashes of bones with tar, and 'gaum' it thick all over their heads and ears and go caterwauling about the hills and call it mourning." You may think that Mark was laying it on a bit thick, but Bancroft backs him up in this statement and says, moreover, that during the frantic orgies a participant would reach into the fire, seize and eat a piece of the half-burned flesh.

It is not to be wondered at that such a people, when the white man brought his contributions of whisky and assorted diseases, fell easy victims. We hear that in Monterey in 1786 *El Mal Galico*, as the Spaniards patriotically called syphilis, was rampant, and the deaths were three times as numerous as the births by reason of it. Stillbirths were especially meant.

Smallpox did its share as well as the great pox, but the mission Indians were pretty well vaccinated. De Mofras says that the colonists, as well as the Indians of the missions who were vaccinated were exempt from intermittent fevers and smallpox. In Wilkes' narrative, 1841, the statement is made that "the ravages of the smallpox two years prior to our visit completed the destruction of these establishments, for it swept off half of the Indians."

All this, however, is mild compared to what happened in the period beginning about 1829 and ending abruptly in 1833. There appear to have been two fairly well-marked visitations, the date of the first rather difficult to fix, but the second almost certainly 1833.

Colonel Philip L. Edwards, whose diary is in the Bancroft collection, writes under date of August 20, 1837: "The intermittent fever sometimes fearfully prevails. Mr. Young (a trapper, whose name is familiar to all students of early California history) informs me that, with a trapping party, he passed one summer here without having one man sick, but that on a trip to the Columbia three years ago with Mr. K. every one of the company, himself excepted, had the fever. We have in our party two or three cases. On every hand we see revolting signs of the fearful ravages. About four years ago it prevailed with such mortality, that the few survivors of the village sometimes fled from their homes, leaving the village literally strewn with the dead and the dying. Mr. Young says he saw hundreds lying dead in one village forsaken by the few survivors, and birds preying upon the uncovered carcasses. The disease seems to have prevailed from the bay of San Francisco to the Columbia in those fatal times. Previous to 1829 it was unknown in the Columbia. Its greatest mortality seems to have been from fifty to one hundred miles interior."

While Colonel Edwards had to accept Mr. Young's tale of what he saw four years before, at least he was an eye-witness of the deserted villages. But there is confirmation from Colonel Warner, who made the statement concerning the thickness of

the Indian population in the valley in 1832: "On our return late in the summer of 1833, we found the valleys depopulated. From the head of the Sacramento to the great bend and slough of the San Joaquin, we did not see more than six or eight live Indians. The disease appeared, as far as I could judge, to be a most acute and violent type of remittent fever."

De Mofras says that in 1834 "a disease resembling cholera broke out and 12,000 Indians died in Tulare, and 8000 in the Sacramento Valley, on the breaking out of a contagious fever." He ascribed the fearful mortality to presence of syphilis generally among the Indians.

The date given by Warner, who came down the valley in the year of the plague, and who had gone up the valley in the year before, finding a numerous healthy population, is probably the correct one, 1833. Colonel Edwards, in 1837, saw the marks of devastation, but got his date from Mr. Young, who said it was four years ago. De Mofras, in 1841, may have been inaccurately informed when he was told that 1834 was the date, though the disease may not have reached Tulare until a year later than the upper valley disaster.

In any event, the reason is plain why the teeming valleys of 1800 had so sparse a population in 1849. What tuberculosis did thereafter does not concern us for the moment. What was the disease that wiped out the Indian tribes? Warner calls it a malignant remittent fever. Edwards, an intermittent fever. De Mofras heard it was a disease resembling cholera visited upon a syphilized people. The fever of which Mr. Young's party suffered was not a fatal one. His party was down, but not out. In Colonel Edward's party one or two were down, but they apparently did not die. The disease which attacked the Indians killed.

Malaria is not to be thought of. It is never so fatal and never comes in such waves. Even races without any acquired immunity do not suffer in such degree. When a Swede gets malaria he is no sicker than a Greek, who ought to have an acquired immunity if any European has. Smallpox would have been recognized by Mr. Young, most likely. Pustules would show on the darkest and dirtiest of diggers. Cholera is not impossible; we have heard those who came across the plains tell of the trail of cholera in 1850. It might easily enough have swept through a valley with a common water supply and the dirtiest tribes on the continent.

Typhus is another possibility and, having in mind what happened to the Fijians in 1876, measles could be thought of. The chance of getting at the truth is small. There were few eye-witnesses, and they were not physicians. The epidemics were not repeated, so far as known, after 1833, and with the great rush of Argonauts in 1849, the Indian was quickly driven to remoter regions, where he has died off in a less spectacular fashion. But this great scourge of the 30's converted a thickly settled country into almost a wilderness. Had the white man not continued coming in greater and greater numbers, the land would have been repopulated in a generation or two, but the discovery of gold brought conditions which this race, no matter how prolific,

could not withstand. Alcohol, syphilis, and tuberculosis finished the work begun by the mysterious pestilence of 1833.

909 Hyde Street.

DEMOCEDES OF CROTONA

By WILLIAM FITCH CHENEY, M. D., *San Francisco*

SOMEWHEN, as H. G. Wells would say, about 600 B. C., in the city of Crotona, a man was born named Democedes, destined to become one of the most famous physicians of his time. He came upon the scene over a hundred years before Hippocrates, the so-called Father of Medicine, and might have filled this place in history himself had more complete records been kept of his attainments and teachings. Crotona was a Greek colony on the southeastern coast of Italy, in what we now call "the toe of the boot." It was a city of power and wealth, and during the century in which Democedes lived was the seat of a medical school considered the best in Greece. We are told by Herodotus that the father of Democedes was a man of savage temper who treated his son so cruelly that he left his home and went to live in Aegina, an island off the coast of Greece. Whether Democedes acquired his medical education at the school in Crotona or elsewhere we are not informed; but "he set up in business," as Herodotus says, in Aegina, and "succeeded the first year in surpassing all the best skilled physicians of the place, notwithstanding that he was without instruments and had with him none of the appliances needful for the practice of his art." His success gave him such a reputation that in his second year in Aegina the government hired his services at the price of one talent a year. This has been estimated about 243 English pounds or approximately 1200 American dollars—in other words, about \$100 a month. In the third year, so great had become his fame, that the government of Athens took him away from Aegina by offering him a salary of 100 minae, about \$2000 a year. Finally, after another year, he was offered and accepted a still more lucrative position with Polycrates, the tyrant of Samos, at an annual salary of two talents. The fact that this ruler, appreciative of ability, persuaded the famous physician to leave Athens and come to Samos, is recounted to his credit; but it proved a bad move for Democedes.

Polycrates was as prominent in the politics of his time as Democedes was in medicine. He rose rapidly from the condition of a private citizen to be the chief power in his country and one of the greatest sovereigns of his age; though like many other despots, of modern as well as ancient times, he had no scruples about the methods he employed to advance his interests. Finally he conceived the ambition to rule not only Samos, but all the islands of the Aegean Archipelago; and this design proved his undoing. There was a wily Persian named Oroetes, who served as governor of Sardis under King Cambyses. When this man learned of the desire of Polycrates, he pretended to be his friend and offered to aid him, inviting him to come to the mainland and talk it over. By his soothsayers, his family, and his friends, Polycrates was urged not to accept

this invitation; but he made light of all their counsel and sailed away to meet Oroetes at the place appointed, the city of Magnesia, on the Maeander River. This would not have been a matter of so much concern, had he not taken with him many of his friends, and among them his own special physician Democedes. No sooner had Polycrates reached Magnesia than he was murdered and his dead body hung upon a cross; and so ended all his schemes. All his followers, including Democedes, were made slaves; and thus the famous physician, sought after by rulers and paid large fees for his professional services, lost for the time not only his reputation and his perquisites, but likewise his liberty and even his identity. It is a satisfaction to know that not long afterwards Oroetes was properly rewarded for his treachery; but that, as Kipling says, is another story.

How long Democedes remained a slave is not clear; but the murder of Polycrates occurred during the reign of Cambyses, and we do not hear of the physician again until Darius became king. Then there came one day a dramatic ending to his obscurity and his chains. For Darius, as he leaped from his horse, sprained his foot. The Egyptian physicians he had at his court, whom he considered the best skilled in the world, could not give him relief. On the contrary, the report is that they twisted the foot so clumsily and used such violence that they only made the suffering worse; so that for seven days and seven nights the king could get no rest or sleep. On the eighth day someone recalled that Democedes, formerly the physician of Polycrates, was now in bonds at Sardis. Darius commanded that this man should be brought at once to him in the royal palace at Susa. He was found among the slaves, uncared for by anyone, and he came clothed in rags and clanking his fetters. But Democedes was wary. He feared that if he demonstrated his skill on Darius and proved his ability, he would be kept in Persia all his life and lose all chance of ever again beholding Greece, his native land. So when Darius asked him if he knew medicine, he answered "No." By this time, however, the king had recalled the physician's name and reputation, and felt assured he was not speaking the truth. Therefore, he ordered his attendants to bring the pricking-irons, with which they were wont to put out the eyes of those who dared to thwart the king's will. Under this threat, Democedes admitted he knew a little about medicine, but he was still diffident. As Herodotus puts it, "He said that he had no thorough knowledge of medicine, he had but lived some time with a physician and in this way had gained a slight smattering of the art." This was enough, however, to satisfy Darius, who placed himself accordingly under the Greek physician's care. Democedes at once employed the remedies customary among his people for such injuries as that of his royal patient, exchanging the violent treatment of the Egyptians for milder means. Very soon he was able to give Darius relief so that he could sleep; and in a few days restored to him the complete use of his foot, after he had quite lost hope that he would ever walk again. The king was so pleased that he told the eunuchs to take Democedes to see his wives and tell them this was the man who had saved his life. Then

each of the wives dipped with a saucer into a chest of gold and gave so bountifully to Democedes, in payment for his services, that a slave who followed him and picked up the coins he dropped, gathered up for himself a great heap of gold.

After this the rags and fetters were exchanged for fine raiment and luxury. The physician came once more into the state to which he was accustomed. He dwelt in a large house in Susa near the king, feasted daily at the royal table, and lacked for nothing he desired; excepting liberty to return to his own country. It is related explicitly that he was magnanimous enough to save the lives of the Egyptian physicians who had failed to cure the king; for Darius, indignant over their clumsiness and the suffering they had caused him, had ordered them all to be impaled alive on sharp stakes. Not only was Democedes able to prevent this, but we are told that after the cure of Darius there was no one who stood so high as the physician in the favor of the king.

But with all this he still was not satisfied, for love of country exceeded his love of place, of power and of money, and he longed to return to Greece. It happened a little while later that an opportunity presented itself, of which he was quick to take advantage. Queen Atossa, the wife of Darius, had an abscess form on her breast. So long as this was of no great size, she hid it through shame and mentioned it to no one. But when it grew larger and more painful she sent at last for Democedes and showed it to him. By this time he was in a position to demand a reward for his services, and told the Queen he could make her well, provided that if he cured her she would urge Darius to make war on Greece and take along the physician as a guide. The abscess was soon healed, and Atossa then kept her part of the agreement by urging her husband to invade Greece and bring her home some of the Athenian and Corinthian and Lacedemonian maids as slaves to serve her, suggesting also that he take along Democedes, who could tell him better than any one else in the world what he wanted to know about Greece. Darius promised to do as she wished, but thought it best to send first some Persians to spy out the land, in company with the man she recommended, to bring back a full report.

So it happened that fifteen Persians of note were selected to take Democedes as their guide and explore the coasts of Greece; but Darius was evidently suspicious, for he instructed them particularly to bring the physician back with them and not to allow him to escape. In the further effort to prevent this, he appealed to Democedes himself, allowing him to take along all the valuables he possessed, as presents to his father and brothers, and promising him on his return a far more abundant store. And finally the king gave him, as a reward in advance for his services as guide, a merchant ship loaded with all manner of precious things, to accompany him on his voyage. So in ships fitted out at Sidon, in Phoenicia, they sailed away to Greece. Arrived in sight of land, they kept along the shore and examined it, taking notes of all they saw, in this way exploring the greater portion of the coasts. At last they arrived at Tarentum, a Greek colony in Southeastern Italy, not far from Crotona. Here the king of the

Tarentines was a friend of Democedes. Out of kindness to him, to permit his escape, he imprisoned all the Persians as spies and took all the rudders off their ships. Democedes then lost no time in getting away to Crotona, his native city, about 150 miles from Tarentum. After this had been accomplished safely, the king discovered that the Persians were not spies after all, and so released them, at the same time restoring the rudders to their ships.

It is easy to understand that what troubled the Persians most about all this was the fact of Democedes' escape, for they remembered the commandment of Darius not to permit this to happen. As soon as they could get away, therefore, they sailed in pursuit of him. They found him in Crotona, in the market place, and attempted to arrest him; but his friends rallied to his defense, beat the Persians with their walking-sticks and drove them off, in spite of their protests and threats. The people of Crotona also seized and retained the treasure ship that Darius had presented to his physician. This seems to have convinced the Persians that they had better not try to make any further explorations of Greece; for with their guide taken away and their property stolen they thought before worse happened it would be well to get back home. As a parting message to Darius, Democedes sent word of his approaching marriage to the daughter of Milo, the famous athlete. This man was in high repute with Darius for his gigantic strength and his ability as a wrestler, and was probably respected more by the king for this than he would have been for intellectual attainments. So this message was to prove to Darius what a man of mark Democedes was in his own country. Thus the story ends, as regards the famous physician, who continued to live happily and prosperously thereafter in the city of his birth. The Persians, however, had many troubles on their way back. They were shipwrecked on the coast of Iapygia and made slaves by the inhabitants, and remained in this city a long time before at last they were ransomed. They found their way home ultimately and reported to Darius, who seems to have forgiven them after all for not bringing his physician with them. At any rate, if he did impale them alive on stakes, no one cared enough about it to record it in history.

210 Post Street.

CAN YOU HELP?

"The History of the Medical Profession of Southern California"

A volume by the above name was printed under the editorship of the late Dr. Walter Lindley and Dr. George H. Kress, back in 1910. Dr. George D. Lyman, 380 Post street, San Francisco, desires to purchase a copy of this for the Stanford University library.

The California State Medical Association, through the secretary, Dr. Emma Pope, is very anxious to have a copy of the same volume for its files.

The Barlow Medical Library, 741 North Broadway, is also anxious to have a copy of this volume for its files.

Anyone in possession of this book, who is willing to either sell the copy to the Stanford library or to donate a copy to our State Medical Association or to the Barlow Medical Library, would do a favor by writing to the above.

CALIFORNIA'S MEDICAL PRACTICE ACTS

By F. F. GUNDRUM, M. D., Sacramento

Doctor Gundrum here tells an ugly and discouraging story of facts that explain many things. Every physician should read and ponder this essay.—THE EDITORS.

THE material herein contained came from the minutes of the Medical Society of the State of California, the records in the office of the Secretary of State and in the State Library, and from the Statutes of the State of California.

The status of the physician—social, economic, and scientific—has varied widely during the past. Depending upon his usefulness to the community, and his opportunity to learn, he has been necromancer, slave, valet, gentleman, scientist. Throughout the ages, also, there have been multitudes of quacks who undertook to heal the sick without the bother of previously learning what there might be available to know concerning the art. These have been either sincere fanatics or mere crooks making a living through the exploitation of the sick. In great measure, perhaps, on account of the presence of unskilled and irresponsible practitioners, there has ever been a more or less vigorous effort to regulate the practice of the healing art. This regulation has been done by physicians themselves through painstaking teaching of medical apprentices by preceptors, of students by medical schools, and through the establishment of "Ethical Codes," such as the ancient oath of Hippocrates and modern similar, if sometimes unwritten, rules. This sort of regulation has been fairly successful. The better men and the better schools have splendid records of conscientious unsurpassed human service. Regulation has also been done, not always to the betterment of medical practice, by others. Earliest and most powerful of all was "public opinion." With a more conventionalized and formal social fabric, more definite supervision appeared. So ancient a document as Hamurabi's Code contains some regulatory sections (i. e., fixes fees). In Colonial America, doctors were relatively few. The apprentice-preceptor system of studying medicine was in vogue, and the then medical practitioners had control in large measure of the number and quality of practitioners to follow them. Later, medical schools grew up, largely owned, operated and controlled by medical men. These thrived, flourished, and many went sadly to seed, putting out very poorly trained men to the dissatisfaction of the profession and public alike. In casting about to find some remedy for this evil, some of our fathers hit upon the idea of having laws passed and licenses issued to all who were worthy. This placed the affairs of medicine into the hands of the states, that is to say, the legislatures, the governors, and, in certain states and of late years, the electors. The course of this regulation in California it is my purpose here briefly to outline. We may, for the sake of convenience, divide the progress of affairs into several distinct phases.

BEFORE 1876—FIRST PHASE—THE STATE TAKES NO OFFICIAL PART IN REGULATING MEDICAL PRACTICE

Before 1876 there was no legal restriction upon the practice of the healing art, and he who was thus

ambitious hung up his diploma, if he had one, in his office and his sign on the door. The sole criteria of success were therapeutic efficiency. This was stimulating and evolutionary. The ultimate control, however, was largely in the hands of the medical fraternity who had been preceptors of these and instructors in their schools. A goodly sprinkling of ill-educated gentlemen undertook the practice of medicine, to the disgust of those other better trained practitioners who saw the unnecessary disabilities, deformities, and deaths due to unskillful handling. Accordingly, there was considerable discussion as to a proper means of limiting the right to practice to those men only who had been sufficiently educated. At the third annual meeting of the California State Medical Society held in April, 1873, J. F. Morris of San Francisco introduced a resolution "that the State Medical Society, desiring to see some system adopted by which a high liberal standard of medical ideals and graduates may be secured, has heard with great pleasure that the State University contemplates an independent Board of Medical Examiners," etc. This motion failed, and at the fourth annual meeting in April, 1874, H. Gibbons, Sr., introduced a resolution "that it is desirable there should be a uniform system for examination of the degree of M. D. apart from institutions of teaching so that diplomas shall be awarded to all competent candidates, and the profession and society at large maybe protected against degrees awarded unworthy and incompetent persons," etc. This motion provided for the appointment of a committee of five, who reported on the following year at the fifth annual meeting, April, 1875. T. M. Logan of Sacramento, then secretary of the State Board of Health, who was chairman of the committee, read the resolution "that it is the duty of and we recommend to the legislature of the State of California to pass a law," etc. This was amended by H. Gibbons, Sr., back to the motion of the preceding year. The amendment was carried and this committee was appointed: Morse, Shurtlegg, Logan, Gibbons, Heuston.

LAW OF 1876

The legislature, at any rate, proceeded to the passage of an "act to regulate the practice of medicine in the state of California," known as Senate Bill 549, introduced by C. W. Bush of Los Angeles, and passed without roll-call, although five members asked to have their names recorded as voting in the negative. Assembly vote: Ayes, 45; noes, 18. This introduced the

SECOND PHASE—CONTROL LEFT IN MEDICAL HANDS, BUT LEGALIZED AND CERTIFICATED UNDER CERTAIN CONDITIONS BY THE STATE

The act provided for the appointment of a board of medical examiners of seven members by each State Medical Society, incorporated and in active existence on the tenth day of March, 1876. These were two—the Medical Society of the State of California, incorporated 1870, and the Eclectic Medical Society, incorporated 1874. Every person practicing medicine was required to present his diploma to the Board of Examiners for verification as to its genu-

ineness. If the board decided that the diploma was genuine, certificate to practice was to be granted. In case a practitioner had no diploma, he was compelled to submit himself for examination to the Board of Examiners. Should he appear to them to be sufficiently well qualified to practice, a certificate was issued without diploma. This privilege of examination for non-diploma holders expired December 1, 1876. The boards were enjoined to notify county clerks, who must keep a record of licensed practitioners within their counties. The fees received by the boards were turned over to the medical society appointing them. The procedure to be had for verification, refusal, or revocation of license, together with penalty for illegal practice, was provided for. Revocation could be had for "unprofessional and dishonorable conduct," details not entered into.

AMENDMENT OF 1878

The law of 1876 was amended in 1878 so as to include the Homeopathic Medical Society, incorporated 1877. Thus there were three licensing boards, each appointed by and responsible to one of the three then existent State Medical Societies. This amendment required an affidavit executed by each applicant presenting his diploma, to the effect that the medical institution granting the same was at the said time a legally incorporated institution actually and in good faith engaged in the business of medical education, etc. It discouraged itinerant practitioners by a fee of \$100 a month, but did not alter the control of medical practice. "Unprofessional conduct" could be decided by expert witnesses. These three boards continued in operation for twenty-three years.

LAW OF 1901—THIRD PHASE—THREE BOARDS ARE FUSED, REQUIREMENTS RAISED SOMEWHAT, EXAMINATION DEMANDED—THE DOCTORS STILL APPOINT THE MEMBERS

In 1901 the state legislature passed a bill introduced by D. W. Hasson of Buena Park, Orange County. The vote in the Assembly was: Ayes, 60; noes, 2. Senate: Ayes, 22; noes, 5. This bill became a law under a constitutional provision without the Governor's approval on the 27th of February, 1901.

There was established a conjoint board consisting of five members elected by the Medical Society of the State of California, two by the Homeopathic Medical Society, and two by the Eclectic Medical Society, nine in all. Six affirmative votes were required for any act or resolution. This provision forced the adherents of the different so-called "schools of practice" into some sort of accord, no business being possible else. The requirements for the applicant were somewhat increased. He must now submit:

1. Testimonials of good moral character.
2. A diploma issued by a regularly chartered medical school conforming with the then standards of the Association of the American Medical Colleges.
3. Affidavit stating that he was legal possessor of the same diploma.
4. To personal examination by the board, at least

part in writing. Certificate issues by the District of Columbia or any state or territory of the United States whose standard was equal to that of California could be accepted and registered. The procedure of revocation of license was set forth, together with the compulsory filing of certificates with the county clerk. Unprofessional conduct (seven items) was defined, also illegal practice.

LAW OF 1907—FOURTH PHASE—GOVERNOR APPOINTS FROM ELECTED MEMBERS OF MEDICAL SOCIETIES

In 1907 the Senate Bill 238, introduced by H. S. G. McCartney of Los Angeles, passed without a dissenting vote in either Senate or Assembly, was approved March 14, 1907, by the Governor and superseded the law of 1901.

This act removed the regulation of medical practice still further, but not entirely, from the doctors. It provided that the Governor should appoint a board of medical examiners consisting of eleven members, five members from a list of ten presented by the Medical Society of the State of California, two from a list of four presented by the Eclectic Society, two from a list of four presented by the Homeopathic Society, and two from a list of four presented by the Osteopathic Association, which had in the meantime been incorporated (January, 1901). No person in any way connected with a teaching institution was eligible to this board, and the vote of seven members was necessary to carry any motion or resolution or issue any certificate. Three certificates were authorized:

1. Medicine and surgery.
2. Osteopathy.
3. Any other mode or system.

Each applicant was required to produce his diploma from a school whose qualifications were those of the Association of American Colleges of even date, testimonials of good moral character, affidavit attesting ownership of the diploma, and to undergo a written examination, the subjects for which were specified. The recording, revocation, unprofessional conduct (seven items) penalties for violation were also provided.

"SPECIAL" AMENDMENT No. 1

The act of 1907 was specially amended in 1909. This amendment introduced by Senator Savage, and carried unanimously by both houses, set forth in detail who may practice medicine in the state of California, namely: All licentiates under all previous acts, and also "any person who holds an unrevoked certificate issued by the Board of Examiners of the Association of Naturopaths of California." The scholastic, medical, moral, or other prerequisites to the acquiring of this certificate are not stated.

"SPECIAL" AMENDMENT No. 2

The act of 1907 was specially amended again in 1911, instructing the Board of Medical Examiners to issue a license "to any person who has practiced his special branch of medicine for a period of not less than thirty-five years, fifteen years of which shall have been in the state of California upon affidavit that he has successfully and effectively prac-

ticed the special branch of medicine and surgery for the number of years herein mentioned," etc. All other persons must take an examination, the subjects and marks of which are set forth. Penalties for purchasing or altering diplomas were provided for.

LAW OF 1913—FIFTH PHASE—STATE SOCIETIES NO LONGER RECOGNIZED

Senate Bill 813, introduced by J. L. Avey of Redlands, passed the Senate, ayes 21, noes 18; Assembly, ayes 46, noes 0, and was approved June 2, 1913. In the terms of this bill, the legislature took no further cognizance of the state medical organizations, but provided for a board of ten members, appointed by the Governor, all citizens of the state, no restrictions as to form of license held; however, persons connected with medical teaching institutions were not eligible. Seven votes were necessary to carry any motion. The board was authorized to issue three certificates:

1. Physicians and surgeons.
2. Drugless.

3. Reciprocity certificates (a new departure in California, and ordered issued upon license in other states whose laws are equal in requirements of those of California of even date). The requirements exacted from the applicants for licensure were increased by a high school diploma to be succeeded (after January 1, 1919) by one year of college work in science before entering medical school. The bill contained a long and detailed statement of the number of hours' instruction in each subject for both physician and surgeons and drugless certificates. Thus relieving (by legislative mandate) college faculties from the strain of deciding upon curricula. The subjects for examination were set forth. A provision for raising the drugless certificate to physicians and surgeons by subsequent examination was inserted. There is also in this act another innovation, namely, the oral examination by a committee of the board of practitioners licensed in other states before August 1, 1901. This provision took care of the elderly practitioner long out of school who, though possibly a highly competent physician, had considerable difficulty with the written examination, particularly in pre-medical and pure scientific subjects. Suspension, revocation, recording procedures, and an official directory were provided for, and "unprofessional conduct," now eleven items, defined.

AMENDMENTS OF 1915—BOARD AUTHORIZED TO SELL DIRECTORIES—CHIROPODISTS LICENSED UNDER THE BOARD

The act was amended in 1915 to rearrange the meeting places and give the board authority to sell official directory of licensed practitioners which the board had been compelled to compile under the 1913 act. These amendments also defined chiropody and provided for the issuance by the board of certificates to chiropodists, with the usual proviso that for ninety days after the passage of the act all chiropodists who have practiced one year may register without examination; stated further the requirements for chiropodists, as well as reduced the numbers of hours of instruction for the other certificates. The

requirements preliminary to the examination for drugless certificates were reduced to a one-year course and three years of actual practice in the state of California. Six years of practice and one thousand hours instruction now entitle an applicant to a drugless certificate. The entering into contracts of reciprocity with other states was permitted (another innovation). The varieties of unprofessional conduct were increased to twelve.

AMENDMENT OF 1917—SIXTH PHASE—DOCTORS
NOW PAY A YEARLY LICENSE FEE—MID-
WIVES LICENSED UNDER THE BOARD

This act was again amended in 1917, a very long amendment introducing another innovation, namely, the yearly collection of a two-dollar license fee from all licentiates under the preceding laws. The penalty for overlooking this two-dollar tax for sixty days is only the forfeiture of the license. The act also defined the practice of midwifery, and authorized the board to issue certificates to midwives; set forth again the educational qualifications for applicants desiring either physicians and surgeons, drugless, chiropodists and midwifery certificates; detailed the number of hours necessary, the type of examination and the subjects; authorized the board to issue a midwife certificate upon one-year practice and good moral character; allowed holders of osteopathic certificates to be given an oral examination in order to raise a certificate from drugless to physician and surgeon. This provision seems in large measure to nullify the salutary effect of the additional requirements for a physician and surgeon certificate. If any license granted before March 4, 1907, had been refused acceptance in California because of insufficiency of state standards of licensing, the applicant might receive an oral examination. We find further addition to "unprofessional conduct," which amounts now to eighteen items. Somewhat astonishing is the variety of things for which a midwife's certificate might be revoked. Apparently, one of these might lose her license if she forgot her nail-brush, or if the scissors she used for cutting the cord had points.

AMENDMENTS OF 1919—SEVENTH PHASE—BOARD
OF EXAMINERS' DECISION AS TO QUALIFICA-
TIONS OF ANY MEDICAL SCHOOL NULLIFIED

This much-amended act of 1913 was re-amended in 1919 to allow a student in a regular chartered medical school to treat the sick and afflicted without compensation, etc. Again, in 1919 to provide that, if any school be disapproved by the board, such school could commence an action in the Superior Court; the court to have full power to investigate, and its action take precedence over that of the board. This law left little control of medical education and practice to medical men.

INITIATIVE MEASURES OF 1923

At the general election in 1923 initiative measures, fathered by the osteopathic and chiropractic practitioners, were carried, establishing separate boards of examiners for these astute gentlemen who

at least have gotten away from the biennial wrangle at the legislature.

SUMMARY AND CONCLUSIONS

Thus, during the past fifty years the control of California's medical affairs has drifted steadily from the hands of practitioners of the healing art into the hands of others (mainly lawyers). The chief reason assigned for all this legislative activity has been "limiting the right to practice the healing art to those only who have adequate education to make them safe advisors." Musgrave, in a recent number of CALIFORNIA AND WESTERN MEDICINE, estimates that there are now operating about one "doctor" of some sort to each 100 of population; about 31,000 altogether. Of these, only 8000 (a little more than one-quarter) hold physicians and surgeons (that is unlimited) licenses, and possibly 19,000 no license at all.

Those of our fathers who put their trust in a licensing system to preserve the ideals of medical men, namely, a well-educated profession, were, the event has proved, most misguided. The method does not produce such a result. It is not likely that legislation of any sort will be any more successful. The age-old test of therapeutic efficiency will, however, still be with us to test the merits of medical ideas. Fifty years ago the best doctors did the most work. They do now. Intelligent students will nearly always go to the best medical schools attainable, and laymen (most of them) will employ the most able available medical advisors.

Capital National Bank Building.

"LET ME LIVE OUT MY YEARS

"Let me live out my years in the heat of blood!
Let me die drunken with the dreamer's wine!
Let me not see this soul-house built of mud
Go toppling to the dust—a vacant shrine!

"Let me go quickly like a candle-light
Snuffed out just at the heyday of its glow!
Give me high-noon—and let it then be night!
Thus would I go.

"And grant me, when I face the grisley thing,
One haughty cry to pierce the gray Perhaps!
Let me be as a tune-swept fiddlestring
That hears the Master Melody—and snaps!"

—JOHN G. NIEHARDT.

The South and North of California Have in Common the First Medical Pioneer and Booster—The first nordic practitioner who arrived in the little pueblo, "Nuestra Senora la Reina de Los Angeles," was John March (Don Juan Marchet), who arrived from Massachusetts in 1836. His fees consisted of horses, cattle, and hides. In 1837 he established himself on the Rancho Los Medanos near Monte Diablo, Yerba Buena, now San Francisco. A letter of Doctor Marsh was published in 1840 in Missouri, and thus he became instrumental in the organization of the first immigrant train to cross the plains to California. It is gratifying to know that the South and the North of California have in common the first medical pioneer and booster. Let us preserve now and forever the same spirit of unity in our medical progress and in the growing prosperity of our great state.—William Wenzlick, M. D.

Old Lady—I believe in post-mortems. It is awful not to know what you have died of.

ADDRESS DELIVERED BY DR. EMMA L. MERRITT AT A BANQUET GIVEN BY WOMEN PHYSICIANS, OCTOBER 11, 1924, IN HONOR OF THE EIGHTY-THIRD BIRTHDAY OF DR. LUCY MARIA FIELD WANZER.

Women in medicine have come into their own in California to a degree probably not equaled elsewhere. There cannot be, of course, a sex line in the practice of medicine, and all fair-minded persons have long since recognized that fact. That it is a fact in practice, at least in California, was well demonstrated when the American Medical Association was our guest. For that great convention the women physicians themselves requested to serve on mixed committees rather than have separate committees.

It is interesting and significant in medical progress that more than three score women physicians recently gathered at the banquet table to eulogize Doctor Lucy Maria Field Wanzer, one of the pioneer women physicians. It was at this banquet that Doctor Merritt presented the following bit of medical history.—THE EDITORS.

IT WAS in the year 1873 that our revered and honored guest of the evening applied at Toland College for admission as a medical student.

You women of the present day do not realize the struggles and hardships undergone by the women who first tried to get a proper medical education. To have lived in the time of those of us who are over 60 has been like living in a dream, so unreal and extraordinary have been the changes that we have seen.

The struggle to practice medicine was only a branch of the great struggle for the general enfranchisement of women. To get even a higher education, with no thought of making use of it outside the home circle, was considered unwomanly, and she who possessed any degree of learning was ridiculed as being a blue-stocking.

I was not one of that pioneer medical group. By my time the path had already been blazed and made easy, but I am old enough to have had the privilege of knowing many of these brave women—Dr. Emily Blackwell, Dr. Maria Zakzewska, Dr. Alida C. Avery, Dr. Helen Webster, Dr. Mary Putnam Jacobi, and others who had immediately followed them in the East; in this state I knew Dr. Buckle, Dr. Curran, Dr. Follansbee, Dr. Charlotte Blake Brown, and the first woman to graduate from a California Medical College and the first to enter the San Francisco Medical Society—Dr. Lucy Maria Field Wanzer.

Toland College was at the corner of Stockton and Francisco streets, the City and County Hospital down a street by the side of it. Dr. Toland had donated the college to the University of California. About one year after it was turned over, Dr. Wanzer, together with her friend, Miss Mary Frazer McDonald, applied for admission.

They had two friends to advise them, Mr. John Swift and Rev. Horatio Stebbins, regents of the university, who instructed the two women to say nothing, but first to apply to the Medical Department, and if they were turned down, then to apply to the regents. They sought the Medical Department, and were refused. They then went to the regents, who referred the matter to their attorney, who looked it up and said there was no law against

it, as the organic law of the state was that both sexes were to be educated if they so desired in the university, and as Toland College was an integral part of the university, the two women could not be kept out. Four months had been consumed in arriving at this decision.

Miss McDonald did not go in. She got tired of waiting—Cupid took her off. She got married and that ended her medical career. Dr. Wanzer told her it was an awful thing thus to desert her, but once her path has been clearly defined, Dr. Wanzer has never been known to turn aside, whatever the obstacles. She is born of fighting stock—her mother of New England revolutionary ancestry; her father of early Colonial period.

Her father as a boy apprenticed himself to Jones, a watchmaker and jeweler in Greenfield, Massachusetts, where he learned his trade. In 1837 he took to Milwaukee, then little more than an Indian village, a stock of cheap jewelry, showy brass beads, glass beads and the like. He was so successful in selling these to the Indians, that Jones finally broke up his business in Greenfield and moved to Milwaukee, where Storer Field married his daughter Lucy Ann and where their first child, Lucy Maria, was born October 11, 1841.

Field continued in the jewelry business till he fell ill, and was advised by his physician to seek life in the open. He became a farmer in Dane County, six miles out from Madison, where the howling of the wild wolves could be heard outside their house, built of rude logs, and with blankets at the openings for doors. He was justice of the peace for Dane County and member, from there, to the legislature.

Her father declared his girls must be capable women. So at the age of 10 Lucy was sent to her mother's sister, Mrs. Brooks, who lived in Milwaukee, to school. Afterwards she went to Madison to boarding school; later to Hartford, Connecticut, where she graduated from the high school. She could go no higher because college courses were not open to women at that time.

The mother was ill in those days, of what was called lung fever, and many a time the little daughter mounted a box and kneaded the bread for the baking under the mother's direction from her sick-bed. She nursed her mother as well. Her mother would praise her for the care. The little girl thought how fine it would be to do things when anyone was suffering. And the years of her mother's illness to follow, as likewise that of her father, only served to feed the flame of her desire some day to become a physician.

In 1858 the family came to California on account of the mother's health; eight in all—the parents, two brothers, and four sisters. The father's money was pretty well gone. He could find nothing to do and was much discouraged. So Lucy, then in her seventeenth year, took the burden of support upon herself by making sleeves in a fashionable dressmaking shop till she got a position teaching in the public school at Temescal, in Oakland, about where Idora Park now is.

The parents moved to Santa Cruz. The father opened up a general store, with one corner parti-

tioned off for the postoffice. He had been appointed postmaster. Though he was officially such, Lucy filled the position and drew the salary.

All the time she was working she was studying. She had private instructors in Latin, French, literature, algebra. She took Latin under a Presbyterian clergyman. Likewise she was saving up money some day to become a physician.

Walter Thorne, afterwards Dr. Thorne, and Lewis Glass had at the time a telegraph office in their drug store. They wanted to give it up, so Lucy, to add to her income, took it over.

She was 23 years of age when she married. She became a teacher in the public school at Santa Clara

Lucy Maria Field Wanzer

and finally the Lincoln grammar school, the best known boys' school at that day in San Francisco.

And now at 33 she stood alone—the one woman in the whole state of California demanding admittance to Toland College.

She went in prepared for trouble, but she did not care. The dream of her life was about to be realized. Some of the professors welcomed her, but the dean told the class that a woman was going to appear and for them to haze her so she could not stay. "Of course, she will complain. We will tell her we are very sorry, but we cannot lecture to two classes. With just one woman we can make short work of it."

The first day she spent from 8 to 12 going through the hospital. Before she got through, some

of the boys were edging away and pulling other boys to one side, so she could see the patients. But some of the "lost links" were trying to carry out the dean's instructions.

The first clinic was a medical one by Dr. Bates. He had a Southern way with him, and he made a nice speech when she entered. That gave her a little standing with some of the boys.

Then came Dr. Toland's clinic. She followed him through one of the wards, and then came the syphilitic and gonorrhoeal ward. He thought perhaps that was too strenuous, that perhaps she would not care to go, but she said, "Oh yes, doctor; I know the work is hard," but she told him she wanted to see everything, otherwise she was not fit to be a medical student.

Then she saw Dr. Martinache and the eye ward. Dr. Martinache told her a woman had no business to study medicine; that if she did she ought to have her ovaries removed. She replied if this were so that the men students ought to have their testicles removed.

Dr. Beverly Cole had the obstetrical clinic. He sent for her, told her he would not like to place her in an unpleasant position, but that he could not lecture to a mixed class without making it very embarrassing to her; that as he was about to commence his course, if she thought best he would excuse her. She told him she wished to be excused from nothing. He was rather pleased, and said if she wanted a preceptor he was perfectly willing for her to be his student. She asked him, "What would be the expense?" He said it would be nothing, but that he could give her advantages that he could not give a young man. So when there was no lecture going on she was in his office. Sometimes he would give her the most trying things to do and would think it a joke. No matter what it was she did it.

She was dissecting for hernia when the boys decided it was about time to haze her. The next morning when she went to the dissecting room she noticed an unusual number of students around. The cadaver had been arranged in a manner that they thought would shock her very much. She took no notice of it and went on working as if nothing had happened.

Then came one of the student's birthday. The boys planned to give him beer enough till he fell asleep. They then carried him after dark into the dissecting room and tied him onto the table. About midnight he woke up and screamed so, the whole neighborhood was aroused. It created such a commotion the faculty had to take note of it. They sent for every student, herself among the number. She told them she was not a detective. The students afterwards said they thought that every woman would blab. That sort of made a comradeship between them, and by the time she graduated there was not one who would not do anything for her.

She graduated in November, the Centennial year, 1876. Dr. Cole presented her name to the County Medical Society. A movement was set on foot to blackball her. She was advised to withdraw her name. She replied: "My name stands; blackball me if you will." They put her name through, the first woman ever presented. Three years previously Dr.

Charlotte Blake Brown had applied for admission, but her name was withdrawn before the time came for voting.

Dr. Wanzer set up immediately an independent office over a plumbing shop at 130 Geary street, right opposite where the City of Paris is now.

She had six rooms for about \$45 a month, and rented out three for \$15, with the understanding that the tenants must clean up the office and answer all calls that might come.

When she graduated the papers were full of all sorts of nonsense, ridicule, and praise, and her friends told her she would make a great success, and that they would help her. But very few sent other than their servant girls. At first she had to practice among the very poorest persons from Tar Flat. Gradually she got a better class. When the mistresses found their servant girls did not die, they came themselves.

That same year she entered the Pacific Dispensary. It was in the basement of the Synagogue on Taylor street, near Post. The next year the dispensary started the Hospital for Children on Post street, between Stockton and Dupont. They had four beds.

Dr. Wanzer remained on the staff of the hospital till the University of California took it over and made a teaching institution of it.

Twenty-two years after her graduation, Toland College was moved to its present site on Parnassus avenue. At the dedication, Dr. Wanzer was amazed at the number of women studying medicine in the building—twenty-two—and each year they had been graduating them for twenty-two years.

Tonight we are over sixty women physicians assembled to do her honor to show our appreciation of her unflagging zeal to duty, of her many deeds of charity, and of her rare devotion to the cause of women in medicine, which has done much to bring about the standing and success of the present-day woman physician.

She was beyond any professional jealousy, which all too often for a personal aggrandizement lessens another's achievement. She always tried to help other women up the ladder, and to push them forward beyond where she had been able to go. She took them to see her cases; she rejoiced in their four years as against her two; their European advantages as against her local; their internship in a hospital, even their professorship in the medical school, as against her struggle to enter.

Possessed of all her faculties, may she live to be 100.

The Way of the Transgressor is Hard—"On November 25, the Indianapolis Medical Society passed a resolution which said that the consultation by any member of the society with any person or persons not graduates of a regular, constituted school of medicine and surgery with a degree of doctor of medicine is a violation of the principles of ethics of the American Medical Association. The owners of Clark-Blakeslee Hospital held that this ruling prevented members of the regular profession from operating at their hospital and hence was a damage to them. They conduct an osteopathic hospital, it is said. A suit was filed against the Indianapolis Medical Society by the owner of this hospital which was decided in favor of the Medical Society."

ORIGIN AND ESSENCE OF THE "LANE MEDICAL LECTURES"

By ADOLF BARKAN, M. D., *San Francisco*

I feel a better man from having carefully studied Dr. Barkan's inspiring message in manuscript. I commend the message and its telling to every physician who loves his profession and his fellow-man.—W. E. MUSGRAVE.

THE records of the history of medicine on the Pacific Coast contain few pages more worthy of being chronicled than those referring to the foundation of the "Medical Lecture Series by Dr. Levy C. Lane in the year 1896. In no small measure have these lectures caused a "Renaissance" of medical

Levy C. Lane, M. D.

education on our coast; they have created an atmosphere of international medical culture and progressive, scientific work.

Honor to the founder!
Honor to the lecturers—

who carried out the founder's far-seeing thoughts.

About the year 1893 a book had appeared, equally important to general, as well as to aural surgeons, William Macewen's classic on the "Pyogenic Affections of the Brain and Spinal System." It contained the ten years' experience of the Glasgow Regius, Professor of Surgery. It lifted the fog of mischievous ignorance which had prevailed heretofore in the field of affections of the brain and central nervous system, and revealed important facts and observations which threw new light on the pathology and therapeutics of brain and spine disorders. A few of us plunged into the study of the book, receiving from it inspiration and instruction. Chronic purulent affections of the middle ear, which for untold times had been neglected and misunderstood, and which, through their continuation to the brain had furnished hetacombs of victims, now assumed a most important aspect. There seemed no other way open

Hirschfelder Barkan Macewen Stillman
Lane
William Macewen demonstrating Macewen's Triangle.

but to study the subject at the fountain-head in Europe. Professor Macewen was to open the discussion on this very subject at the surgical section of the British Medical Association in London a few weeks hence. A quick resolution was taken to meet him there, and a letter forwarded asking for an interview.

A few days before leaving for Europe, Dr. Lane requested that I call at his house, and in the presence of Mrs. Lane stated: "We have concluded to found a course of medical lectures to be given annually by big men in our profession. They are to be ten in number—free to the medical student and practitioners of the coast; they are intended to form an encouragement for study and work. We have reserved a sum of money, the interest of which, \$2000, will be paid as an honorarium to the lecturer. I have the man in mind whom I would like to head the list of lecturers; I want you to bring him out."

What was my surprise and how great the joy at hearing that the man who had just given Cooper Medical College a new home and hospital was going to crown his work by establishing a lectureship open to the best medical talent of the world and thus establish a link that might unite the pioneering practice of the young Far West with the ever advancing and progressive work of Eastern and European medical centers. The thought was so big

and radiant! and there sat the man, deep in humanity and love of his profession, smilingly awaiting what I was to say. The honor and responsibility of being entrusted with such a commission filled my mind for an instant. Instead of asking Dr. Lane whom he had chosen as I should have done in a less agitated condition of mind, the possibility of securing Macewen for the place filled me so that I replied, "I will undertake the task and have the man, Dr. Lane." "So have I," he replied. "Who is your choice?" "Professor Macewen!" "He is mine!"

On the day before leaving, Dr. Lane called at my office; he handed me a slip of paper, which stipulated the program of the newly founded lectureship; it did not mention the honorarium fixed. A couple of days previous to the opening of the session of the British Medical Association, I arrived in London and found a short postal card, in answer to the letter written Macewen. He would arrive on such-and-such a train from Glasgow, and could be found at the hotel. The hour mentioned found me at the door of Professor Macewen's room at the St. Pancras Hotel, modest quarters indeed for a man of such figure and import. To my impression, he expanded and filled every niche of the small room and illuminated every corner of available space. He had nearly finished dressing for a dinner he was to at-

tend at a friend's house, and I remember distinctly his buttoning on his collar when taking Dr. Lane's slip of paper into one of his hands, read it and looked at me, the messenger from the far-off land, California, with a heart-winning, wistful glance of his blue eyes. The message evidently pleased him; I supplemented Dr. Lane's lines with a few explanatory remarks and concluded that the fee attached to the lectures was \$2000. He most good-naturedly, and with a delightful Scotch intonation, remarked: "The fee does not tempt me, but I like the idea." That was it! The Idea! The word and the tone of his voice—the glance of eyes filled my heart and mind—I felt sure that in the end he would accept. For is it not the "Idea," the Ideal, which fills life and makes it worth living? At his request, I jumped with him into the hansom cab; during the long, long drive he asked questions about California, its climate, its fauna and flora, schools, people, topography; he inquired about my own history of getting there, of living among free people; seemed pleased at their still upholding the traditions of the old Vigilantes—on I went, answering as best I could—and, after three-quarters of an hour's drive, I felt like a bag from which every drop had been pressed out, while the bird whom I hoped to bag myself was flying to the retreat of quiet second thought with free wings and a wistful look.

The next morning, an hour before the beginning of the meeting of the Otological Section before which he was to deliver his address on the surgery of the brain, I was in my seat; soon after the spacious hall of Kings College was filled to overflowing by men eager to listen to the master's words; he entered with the chairman of the section. Silence! Enters a messenger with the request that the beginning of this section be postponed a quarter of an hour, for the surgical section intended coming over in a body, a request which indicated the importance of the man and his work, but one which it was impossible to heed, as there was hardly any standing-room. For an hour, Dr. Macewen held his audience spellbound. Pathology, anatomy of the brain, clinical observations, surgical proceedings, clear and direct, the surprisingly positive results of the recoveries in the field of brain surgery, were communicated and the therapeutical suggestions to arrive at them described. A revelation of clear thought and penetrating action! A very few men asked questions even. There stood the noble figure, smiling at the ringing applause, demonstrating to whoever seemed interested in the subject matter, with drawings and chalk in hand. New groups of listeners formed about him, attracted like iron filings by a powerful magnet. From the man's manner of conversation the day before, I had expected much, but the man's flow of speech, his clearness of delivery, the simple earnestness with which he seemed to single out every man in the crowd assembled as his individual listener and student, his voice, his eyes, the noble mould of his face and figure—a surgical savior, speaking to his disciples! It was indeed a divine hour, a holy service!

When everyone had departed, he greeted me with a smile of sympathetic recognition. That quickly made up my mind. It was "Aut Caesar, aut nihil,"

E. S. Cooper.

and shaking hands with him, I said, "Professor Macewen, may I cable Dr. Lane that you accept to deliver the first medical lecture series next year?" He smiled, took me into a corner and, omitting all formality of conversation, mentioned a few points that needed a bit of clearing up—some explanations he would want the members of his family to hear from me when I came to Glasgow, necessary from the fact that being attached as surgeon to the King's person during his sojourn in Scotland, leave for longer absence might be difficult to obtain. He found, however, time to say a few pleasant words about friends in America, and wound up by stating: "Now you go over to the continent and see Schwarze's work. You will hear from me as soon as we have material worth while your coming to Glasgow. We will talk of the matter further. Write to your friends in San Francisco that they may send me a formal tendering of the lectureship." I felt that the seed of sympathetic consideration had been implanted and that it would be both improper and unwise to urge the subject any further. Having sent off a lengthy and enthusiastic report to Dr. Lane, I crossed over to Halle, where Professor Schwarze, another big man, but of a very different physical and mental type from the lovable dweller of the Highlands, albeit a good teacher and severe taskmaster, put me, during a period of many weeks, through a long, daily drill along the labyrinth of the temporal bone, so as to make my own bones ache.

In due time, the longed-for call came from Glasgow. I entered on my double mission of student and agent in re Lane Medical Lectures, the scene now being shifted to the Western Hospital, and Professor Macewen's home circle. These were happy

hours and days indeed. Genial intimacy soon developed on the base of simple hospitality and kindly understanding. The temporal bone in its important neighborly relationship to the brain and its sinuses; Macewen's triangle as a practically infallible guide into the depth of the middle ear by means of the gentle and steady use of searcher and dental burr in its then still simplest form—the quiet, quick, and safe method of entering the brain which snatched many a patient, it seemed, from the very clutches of death. The time spent under the humane clear-cut influence of this original thinker and genial teacher who, with pencil in hand, after many a dinner would explain the doings of the day, illustrate them with drawings, exhort and encourage—the most inspiring and useful study-time of my life was thus spent—gradually confidence was established; the Highland home was visited; prejudices and fears of too fatiguing a trip for the paterfamilias were conquered. I felt hopeful, and thus it came about that Dr. Rixford and myself met our guest some months afterwards on the overland train, eager to do his work and teach.

Almost directly, we escorted him to the old, big lecture hall of the Cooper Medical College. Whilst he was looking about and finding wall-space for his drawings, Dr. Lane came in. For about ten minutes they conversed—then our venerable and loved chief turned to me and with an appreciative expression of his face, shook hands, saying, "The man will do." And so he did. To me, what a feast it was! What an encouragement for the future!

The students and graduates of both medical schools, many visitors from the interior, up and down the coast, drank in Macewen's words to develop directive forces and sources of better work within themselves and the institutions they belonged to. A new era of medical thought and work had been inaugurated on our coast, Macewen as the first, followed by such lecturers as Clifford Albutt, Michael Forster, Manson, Fuchs, and others, brought the far isolated West nearer to the old and wiser medical culture of the East and the trans-oceanic centers. Thus they fulfilled Dr. Lane's most cherished thought.

Blessed be the memory of him who founded—
Blessed be the memory of the men who carried out his work.

2209 Laguna Street.

The Ultraviolet Rays of the Sun—Alfred F. Hess, New York (Journal A. M. A.), concludes his review as follows: Rickets affords an excellent criterion for the investigation of the biologic activity of the sun's rays, for we know within narrow limits the band of ultraviolet radiations that is effective in preventing or curing this disorder. A comparison of the yearly amount of actual sunshine in cities in the temperate zone demonstrates that there is no close parallelism between the incidence of rickets and annual sunshine. It shows, furthermore, that the occurrence of rickets does not depend on an equable distribution of sunshine throughout the year. In the Panama Canal Zone, where rickets is practically non-existent, not only is the yearly sunshine less than in New York, but it is less evenly distributed; there are fewer hours of sunshine during the rainy season in Colon or Ancon than during the corresponding winter period in New York. The determining factor is the quality, not the quantity, of the sun's rays—the amount of intensity of those short ultraviolet radiations which alone are of value in preventing rickets.

EARLY CALIFORNIAN MEDICAL JOURNALS

By EMMET RIXFORD, M. D., *San Francisco*

EARLY California medical journals are a typical product of Pioneer times in California. The men who came during the Gold Rush—who really made the state and gave it its character, its foundation in romance—were strong men, for no considerable number of weaklings could possibly get here. The pioneers may not all have been good men, for their variety was great, but it can safely be said that they were not goody-goody men.

It is true that among the medical men there were many so-called "natural-born doctors," many men—some of them capable, good men—who had no diploma, but there were also not a few college graduates—young men of family, of imagination, of determination, and possessed of that inspiring gift—the pioneering spirit.

It was a time when men stood up, man to man, ready to defend their position, and if we read between the lines it is evident that occasion frequently offered when defense was necessary; a time of rigid medical ethics, when violation of medical ethics brought greater personal censure, greater acrimony.

Many were the pamphleteers, and a spicy history of early Californian medicine might be compiled from even the few pamphlets which have been preserved.

The first really high-class medical journal published in California—and it now constitutes by far the most interesting and important volume in the history of medicine on the Pacific Coast—was the California State Medical Journal, founded and edited by John F. Morse (Sr.), a quarterly of excellent form published in Sacramento in 1856-7.

Its foundation was intimately associated with the organization of the State Medical Society, and its first number contains the full minutes of the meeting of that organization. These minutes are so important historically, the resolutions contained therein so far-seeing and so illuminating, in view of the recent emasculation of our medical law, that they deserve reproduction in our present State Journal.

Here we can only refer to those parts having to do with the founding of Morse's journal.

Pursuant to an invitation addressed to the members of the medical profession throughout the state of California, calling upon them to meet in general convention in the city of Sacramento on Wednesday, the twelfth day of March, 1856, for the purpose of forming a state medical society with auxiliary societies in each town or county, a numerous delegation from the various sections of the state assembled at Pioneer Hall on the date mentioned at 3 o'clock p. m. Seventy-six men answered roll-call, representing sixteen counties of Central and Northern California. Sacramento had the largest representation, numbering twenty-eight; San Francisco next, numbering thirteen. Dr. John F. Morse was elected temporary chairman. A constitution was adopted and under it Dr. B. F. Keene of El Dorado was elected the society's first president.

In an important resolution of declaration of poli-

cies of the new society, offered by Dr. Thomas M. Logan of Sacramento, this paragraph occurs:

Resolved, That a medical journal, conducted in accordance with the spirit of these resolutions, and maintaining a firm and independent stand against the malpractices and delinquencies of diplomatized, as well as all unqualified practitioners, shall receive the support and hearty co-operation of this Association, and that a committee of three be appointed to canvass the whole subject in the premises, and report, before the final adjournment of this Association, some practical plan for the accomplishment of the end in view.

The committee reported at the next session that Dr. John F. Morse had been engaged for some time past in making preliminary arrangements for the publication of an independent medical journal on his own responsibility, and that Dr. Morse would undertake the publication if guaranteed two hundred subscribers at \$5 per annum. Thus the journal was launched.

A few of the historically important matters brought up in the State Society meeting, and appearing in the minutes, may be briefly mentioned: The motion of Dr. J. T. McLane of Yuba City, to memorialize the state legislature to enact a law elevating the board of censors (of the society) into a board of medical examiners; the motion of E. S. Cooper memorializing the legislature to enact a law legalizing anatomical dissection and providing source of dissecting material; of Dr. O. Harvey of Placerville, urging the formation of county medical societies throughout the state.

On motion of Dr. Dustin of Nevada County, Dr. E. S. Cooper was invited to address the society on the experiments made by him in ligating the abdominal aorta in animals. This was the first paper on a scientific subject read before the California State Medical Society.

The journal contains, of course, the constitution adopted by the society, the code of medical ethics of the National Medical Association, a paper by Dr. A. Wierzbicky of San Francisco on the History of Medicine (general), and several by Dr. Thomas M. Logan on the History of Medicine in California. These latter papers expanded into studies in climatology, containing rainfall and temperature tables.

The second number of the journal was late in appearing. The publisher apologized, giving as his excuse the fact that the amount of type in his establishment was so small that the meteorological tables of Dr. Logan, which were nearly ready for the press, had to be distributed to meet the requirements of election returns in the newspaper attached to the publication department, and also to be able to lay before the readers a report concerning a case of laceration of the vagina which was considered too important to wait the issue of the third number. (The importance of the case was largely medico-legal.)

The troubles of the medical editor in California may be inferred from the publication on the last page of the second number a list of the subscribers; those who had paid their subscriptions were marked by an asterisk, those who had not paid, by a dagger.

At the second meeting of the State Society, February 11, 1857, Dr. Cooper, vice-president, presided because of the death of Dr. Keene. Dr. Henry Gib-

bons was elected president. At this meeting Dr. Morse stated his inability to continue the journal, preferring to transfer the journal to the State Society. The society was reluctant to undertake the task of publishing the journal, so it appropriated \$50 from the treasury to lessen the losses of Dr. Morse and started a new list of subscriptions. At the same meeting the secretary was instructed to drop from the roll all members delinquent in payment of their dues.

The society had but one more meeting, that of 1858, before it dissolved, but before this the journal ceased publication. The editor wrote:

"We regret that we must submit the fourth number of our Journal to the world without sufficient encouragement to continue the publication. The regret, however, is palliated with the assurance of relief from continued pecuniary loss and a vast amount of labor and anxiety, which are more agreeable in theory than practice. We had an idea that we were offering the profession a good opportunity for the establishment of a respectable medical journal, but we have not the slightest disposition to defend this idea against any positive or apathetic conviction of the general profession to the contrary."

Dr. Morse's last word is to subscribers:

"If the seventy-four subscribers of our small list who have not paid their subscription have no objection to remit us the amount due, we will receive it with becoming grace. The sum, if sent us, would, of course, materially abridge our losses, and consequently would be a source of convenience. We would not, however, inflict a harsh call upon delinquents in a country in which *five dollars* is getting to be a sum of such embarrassing magnitude and scarcity."

The stirring editorials by Dr. Morse are well worth reading today: one on Pacific Coast diseases and another describing the atrocities of farming out the counties' indigent sick, urging the building of county hospitals, and the cleaning up of those already in existence.

It is interesting to note that Dr. Morse later moved to San Francisco, and in the summer of 1863 became a member of the faculty of the Medical College of the Pacific, founded by E. S. Cooper in 1858.

The Pacific Medical and Surgical Journal had the longest life of any of the early medical periodicals of California. It was founded in 1858, published in San Francisco and edited by John B. Trask and David Wooster. It started out bravely with short original articles by H. H. Toland, J. Morrison, Isaac Rowell, and E. S. Cooper, from which one may judge that Trask and Wooster made a definite effort to preserve harmony in the local profession and have the support of the various factions, but in the third number the editor, Dr. Wooster, objecting to the report before the meeting of the State Society two weeks previously by Dr. E. S. Cooper of the first case of Caesarean section performed in California, and one of the few cases in the world in which the mother lived, published his (Wooster's) account of the case. (Wooster had been called in consultation and had consented to and assisted in the operation.) His account was a scathing criticism of Dr. Cooper.

This is not the place to take up the merits of the controversy, nor does space permit, but the interested reader of today will find, even in Dr. Wooster's account of the case, much that is illuminating in explaining the factional differences which divided

the profession in San Francisco. Dr. Wooster naively says: "We operated (no other physician present), he using the knife."

The after-treatment, in the light of today, is notable, and gives us a striking contemporary picture of the surgery of the fifties. Dr. Wooster says:

"We used diaphoretics, aperients, opiates, carminatives, tonics, stimulants, etc., etc., etc., according to symptoms. After the middle of the fourth day she had porter, California wine, bottled soda, eggs, small birds, mutton chops, loin steaks, rice, etc., etc., as much as she desired. The first three days a single thickness of domestic moistened in cold water is applied to the exposed abdomen, over the wound to get the refrigerating action of evaporation. As soon as suppuration is established, this dressing is replaced by a warm poultice of bread and milk, which is continued until she is well. A weak dilution of chloride of soda was several times injected through the vagina into the womb, from which it issued at the abdominal wound and did not return by the natural passages. These cleansings diminished very much the almost gangrenous foetor of the first days of suppuration. The abdominal flatus was drawn off by an esophagus tube per rectum. A silver catheter remained constantly in the urethra, by which the bladder was always kept nearly empty. The bladder was incised, at first accidentally, then purposely, during the operation, before the womb was reached. These slight openings closed kindly, by first intention."

It may be noted that the woman was 36 years old, primipara, in labor fifty-six hours, the presentation occipito-posterior. Ergot had been given. No progress had been made for twenty hours. The woman recovered and was able to walk in forty days; the child weighed eleven and one-half pounds.

After the publication of this article, Dr. Cooper did not contribute to the Pacific Medical and Surgical Journal. Thus we get a side-light on the savage criticism which appears in the journal on the Medical College of the Pacific which Cooper organized later in the year.

Nearly every number contained an article or case report by Dr. Toland, often illustrated by excellent lithographs by Britten & Ray.

The journal published annually a register of physicians in the state.

In the second volume, the journal published a caustic criticism by Dr. J. D. B. Stillman of the quality of medical literature served to the medical profession in the journal, showing by the deadly parallel where Dr. Toland got his material. Toland replied—plausibly, but with argument *ad hominem*. The two articles are spicy reading, and at the end the editor closes with the words: "If our friends wish to quarrel or fight, we recommend gunpowder and lead, not types and printer's ink."

A number of articles, entitled "Historical Sketches," by V. Fourgeaud, show much discriminating reading and are noteworthy in the history of medicine.

From its beginning, the Pacific Medical and Surgical Journal seemed fated to change sides, being alternately the organ of one institution or another.

After Cooper's death in 1862, the Medical Col-

lege of the Pacific lasted but two years. The students all went into the newly founded Toland Medical College, and several members of the faculty followed, notably Dr. L. C. Lane and Dr. Henry Gibbons. In April, 1865, the Pacific Medical and Surgical Journal united with Cooper's little journal, the San Francisco Medical Press, under the editorship of Dr. Henry Gibbons. It then might be considered the organ of Toland Medical College.

When Lane and Gibbons seceded from the Toland College in 1870, reorganizing the old school, the journal went too, and remained, as it were, the organ of the Medical College of the Pacific for the next forty years.

Under the editorship of Henry Gibbons and Henry Gibbons, Jr., in 1884, it absorbed the San Francisco Western Lancet, and Dr. Henry Gibbons, Jr., the editor, associated with himself in the conduct of the journal Dr. Whitwell, then editor of the Lancet.

Whitwell eventually took the journal and presently sold it to Dr. W. F. McNutt, then Professor of Medicine in Toland Medical College, by this time the University of California Medical Department. So the journal in turn became the organ of the University of California Medical School.

Dr. McNutt associated with himself Dr. Winslow Anderson, who succeeded to the journal, taking it with him when he left McNutt. Anderson organized the College of Physicians and Surgeons in San Francisco, and the journal became the organ of this new school. Under these auspices the journal lasted a number of years, dying in 1917, ending a continuous life of some fifty-nine years, in its earlier and middle periods being well edited and having a marked influence in medical professional matters in the state of California.

Not the least interesting of the early medical periodicals is the San Francisco Medical Press, published by Dr. E. S. Cooper, beginning January, 1860.

In the light of the above, Dr. Cooper's statement of his objects in establishing a medical journal in San Francisco is amusing:

First. To encourage unanimity of feeling and concurrence of action among medical men of this city and state, in the organization of new, and in perpetuating the old associations for medical improvement.

Second. To inquire into and remove, as far as possible, the sources of discord which have reigned to so great an extent in these organizations.

Third. To vindicate the rights of all honorable medical men when unjustly assailed.

Fourth. To offer a medium for the publication of the numerous interesting and often anomalous cases treated by practitioners on this coast.

Fifth. To encourage medical men of the Pacific Coast to extend their subscriptions to medical journals of the Atlantic States and Europe.

The design is more to furnish original articles than to reproduce those which have already been published in medical journals. To accomplish the above objects, Dr. Cooper promised "to labor for these results uninfluenced by passion, fear or favor." It is evident that Cooper was still smarting under

the attack of the malpractice suit, and felt that he needed a medium of publication of his original work.

This original work is historically of great interest, including as it does considerable surgical experimentation on animals. Cooper advanced, with considerable blare of trumpets, a number of new surgical principles, of which several are important: One, that admission of air into joints is not a cause of irritation or injury; that division of entire ligaments about the joints is no impediment to their ultimate strength and mobility; that large wounds of joints are less serious than small; that early and wide incision of joints is far more imperiously demanded than opening of other parts similarly affected.

After Dr. Cooper's death in 1862 at the age of 40, the Press was edited for a short time by Dr. L. C. Lane, the last volume by Dr. R. Beverly Cole and Dr. Henry Gibbons.

The Western Lancet, founded in 1862 by E. Trainor and H. P. Babcock as editors, in Volume 9 became the San Francisco Western Lancet, with Dr. A. W. Perry and William H. Mays as editors, and in Volume 10, Dr. W. S. Whitwell.

It was a monthly of pleasing form, but had a small circulation. In 1884 it was merged in the Pacific Medical and Surgical Journal.

Another ambitious attempt to furnish for the medical profession of California a dignified medium for publication was the California Medical Gazette, a small quarto which endured for only two years. Volume 1, 1868, names as editors Thomas Bennett, J. Campbell Sharpe, and W. F. McNutt; the second volume, J. D. B. Stillman and W. F. McNutt.

The Pacific Record of Medicine and Surgery, founded by Dr. C. W. Moore in 1886, lived for some twenty years. In the beginning it was published in two languages, English and Spanish, in parallel columns. In 1898, after the death of Dr. Moore, Dr. Louis A. Kengla became editor; he changed the form from a handsome quarto to a less attractive, but probably more useful large octavo. In 1904, Dr. Kengla combined this journal and the Occidental Medical Times under his editorship.

In the more peaceful and constructive middle period of medicine in California the field of medical journalism was occupied by the Occidental Medical Times. Founded in 1887 by Dr. J. H. Parkinson as a modest local journal under the title, The Sacramento Medical Times, it soon found that its statewide field required a change of name. This was made in 1889, in its third volume. Twelve volumes were published when it was removed to San Francisco, uniting with the Pacific Record of Medicine and Surgery, as stated above, under the editorship of Dr. Louis A. Kengla, who had rejuvenated the latter journal. Ceasing publication at the death of Dr. Kengla, it had furnished for seventeen years a most excellent journal worthy of better support than it received. Its influence for better medicine in California and its influence on legislation are worthy of more space than can here be given to it.

Reading between the lines, one can appreciate that the story of medical journalism in Califor-

nia is the story of editorial enthusiasm and infinite but altogether unrequited devotion and self-sacrifice struggling against a dead weight of apathy on the part of the medical public which is difficult to understand.

Only in recent years has the medical profession, as organized in the California Medical Association, given to a local journal the support and appreciative co-operation it deserves.

1795 California Street.

By JOHN HOMER WOOLSEY, M. D., *San Francisco*

EDITORIAL INTRODUCTORY NOTE

The original plans for an historical number of CALIFORNIA AND WESTERN MEDICINE provided for a number of brief sketches of the lives of medical Argonauts of California. All realize that much of what is most stimulating and helpful in medical history is reflected in the lives of medical leaders. Many such have acted their parts in the drama and romance of medicine, with the Golden West as the stage. The men and their doings are well known to those still living, but it is very difficult to find those who care to tell these useful stories.

The following brief sketch of the life of one of these medical Argonauts, whose memory is still much revered, is supplied by one of his students.

William Watt Kerr, of Scotch ancestry, educated at the University of Edinburgh, came to California

William Watt Kerr

in 1881 to begin his life's work. Starting in an humble way he rose, by 1887, to a conspicuous place in the field of Western Medicine as Professor of Therapeutics in the University of California Medical School. The following year he assumed a new title—Professor of Clinical Medicine—and contin-

ued as such to the time of his death. He was one of the leaders of his time. By direct teaching to students of medicine, by co-work with the medical profession at large, and by example he did much in keeping Western Medicine progressive and beholden to high ideals.

"Daddy" Kerr, as he was known to students, always enjoyed young people. Those close to him are familiar with his continuous endeavor to stimulate and to assist young men to further advance in medicine. His presentation of patients at his clinics were always an attraction, and it has been said that of all those present he was the most devoted student. His written contributions testify to his intense interest in medicine and his progressive spirit. Ever modest of his own ability and deeds, he allowed the facts alone of his works to speak for themselves.

His written contributions are as follows:

- Capillary circulation and stasis. *West. Lancet*, 1882, V. 11:486-534.
 Abattoirs. *West. Lancet*, 1883, V. 12:433-447.
 The value of drugs in the treatment of disease. *Pacific M. and S. J.*, 1884-5, V. 27:193-201.
 Cases of fatty heart. *Pacific M. and S. J.*, 1885, V. 27: 213-217.
 Treatment of pulmonary diseases by gaseous enemata. *Pacific M. and S. J.*, 1887, V. 30:339-344.
 Gangrene of the esophagus. *Sacramento M. Times*, 1888, V. 2:1.
 Treatment of aortic aneurism by Loretta's method combined with electrolysis. *Occidental M. Times*, 1889, V. 3:1-4.
 An interesting case of cerebral tumor. *Occidental M. Times*, 1890, V. 4:59-63.
 Digitalis in the treatment of croupous pneumonia. *A. M. A. Journal*, 1894, V. 23:148-151.
 Tachycardia. *South. Calif. Pract.*, 1896, V. 11:161-166; *Tr. M. Soc. Calif.*, 1896, V. 26:36-47.
 Two cases of trichinosis with eosinophilia. *Phila. M. J.*, 1900, V. 6:346-348.
 Obstruction of the inferior vena cava. *Occidental M. Times*, 1897, V. 11:661.
 Cases of angina sine dolore, due to diseases of the right ventricle. *Occidental M. Times*, 1898, V. 12:241-247.
 Typhoid meningitis. (With Moffitt.) *A. M. A. Journal*, 1899, V. 32:603-605.
 Clinical lecture. Plague. *Occidental M. Times*, 1900, V. 14:311-316.
 In Memoriam. An address in memory of Professor R. Beverly Cole. *Occidental M. Times*, 1901, V. 15: 35-37.
 Tropical diseases in California. *Calif. State J. M.*, 1902-3, V. 1:174-179.
 Renal tumor. *Occidental M. Times*, 1903, V. 17:444-446.
 Hodgkin's disease. *Occidental M. Times*, 1903, V. 17:443.
 Diagnosis of diseases of the gall-bladder. *Occidental M. Times*, 1903, V. 17:1-7.
 Myocarditis with special reference to disordered metabolism. *Calif. State J. M.*, V. 2:339-343; 339, 369; V. 3:16. 1904-1905.
 A case of pleural and pericardial effusion. *Calif. State J. M.*, 1906, V. 4:300-303.
 The intensity of the pulmonic sound in mitral incompetence. *Calif. State J. M.*, 1907, V. 5:192.
 The medicinal treatment of myocarditis. *Calif. State J. M.*, 1908, V. 6:17-21.
 Painless and painful angina pectoris. *A. M. A. Journal*, 1909, V. 52:1744-1746.
 Aortic regurgitation. *A. M. J. M. Sc.*, n. s., cxlii:550-558. 1911.
 "Acute cholecystitis. *Calif. State J. M.*, 1911, V. 9:96-99.
 Inter-auricular or inter-ventricular deficiency of septum? A question of diagnosis. *Calif. State J. M.*, 1913, V. 11:156-159.
 Gastro-intestinal symptoms in disease of the circulatory system. *Calif. State J. M.*, 1915, V. 13:345-348.
 Notes on angina pectoris. *Calif. State J. M.*, 1915, V. 13: 301-306.
 Case of pellagra. *Calif. State J. M.*, 1915, V. 13:154.

Some factors in the treatment of myocardial lesions. *A. M. A. Journal*, 1911, V. 57:1517-1521.

Danger of baths in patients suffering from arteriosclerosis. *Calif. State J. M.*, 1916, V. 14:279.

Some heart problems suggesting the necessity for a closer alliance between the physiologists, bio-chemists, and clinician. *Calif. State J. M.*, 1917, V. 15:283.

In 1916, while visiting at certain mineral springs, he first learned of the condition that eventually caused his death. Despite the danger to himself, he proceeded immediately with a series of these hot baths in order to determine their effect upon angina pectoris. Later in March, 1916, he presented these observations to his County Medical Society, but as of the third person, so inborn and noble was his modesty.

His final moment came as he always wished, while active in his care of others. Thus William Watt Kerr, a man of simple taste, untiring in his service to others in need, pioneer in Western Medicine, embodied in his life all that was noble and all but died that others might live.

DOCTOR BENJAMIN F. KEENE

At the Fifty-second Annual Session of the California Medical Association, held in San Francisco, June, 1923, the House of Delegates authorized the appointment of a committee to consider the question of repairing the last resting-place of the first President of the Medical Society of the State of California, Doctor B. F. Keene at Placerville, the lower portion of the old headstone having disappeared. The chairman of the Council, James H. Parkinson, appointed as members of this committee: W. A. Reckers, M. D., chairman, S. H. Rantz, M. D., and Mr. Louis Reeg.

Upon investigation the committee reported that "the grave is overgrown with grass and weeds, the mound is sunken down, the headstone is broken off, and the inscription is partly effaced. The broken headpiece bears the words, 'Here lies the body of Dr. J. B. Keene, the first president of the California State Medical Society.' Also the time of death, etc." The committee recommended that "the entire grave be covered with concrete and that the old broken headstone be placed flatly upon the concrete tomb. Also that the State Society erect a new headstone and place upon it an appropriate inscription."

Upon recommendation of the committee, the Council authorized the repairing of Doctor Keene's grave as shown in the following illustration.

OBITUARY

(Extracted from California State Medical Journal,
October, 1856)

"With feelings of deep regret, we are forced to acknowledge the sudden death of the worthy president of our State Medical Society, Doctor Benjamin F. Keene of Placerville, El Dorado County, on the evening of September 5. The doctor retired to bed in the apparent enjoyment of his usual health, and even evincing an unusual buoyancy of spirits. In the morning he was found dead in his bed. He had previously severely suffered from an attack of paralysis, and the probability is that his death was a consequence of a second recurrence of the malady.

"We have never found a member of the profession more highly endowed with all that constitutes a gentleman and well-informed medical man. Although of a serious and grave cast of character, yet his heart seemed warmed towards his fellow-beings with a benevolence and confidence unmarred by suspicion and unaffected by the admonitions of experience. The calm of a sunny yet deep fellowship seemed ever to be asking expression from every word and act that related him to the world."

Extracted from minutes of the Second Annual Session of the Medical Society of the State of California, held in Sacramento, California, February 11, 1857, as published in "Transactions of the Medical Society of the State of California for 1857":

Doctor O. Harvey paid the following tribute to the memory and character of Doctor Keene:

"It has been my fortune to have been intimately connected and associated with the late-lamented Doctor Benjamin F. Keene from the earliest history of this country to the time of his death, and to have assisted, too, in the practice of that noble profession which we are now representing. And I may add that it has been the misfortune of many, as well as myself, to lose in him one of the noblest and dearest of friends.

"Doctor Keene came to this country from the state of Georgia in the year 1849, and like most men, professional or otherwise, engaged in the pursuit of mining; but from his high professional attainments he soon succeeded to an enviable practice and reputation in the profession which he has ever maintained.

"Some portion of his life has been connected with the political history of this country. Four years he represented the county of El Dorado in the Senate of this state, with that ability, honesty, and fidelity known to but few; and had his life been spared one day longer, he would again have been chosen to represent a confiding constituency in the councils of this state.

"A short time before his death he was foremost in issuing a call to form a medical society in the county in which he lived, of which he was an ardent and working member. His devotion to science, his application of useful knowledge, had no bounds; he was a model for any of us to imitate. His character as a man of honesty, integrity, and morality, was beyond reproach. As a man of amiability and high social qualifications, he scarcely had an equal. Friends he had many—enemies none. To know him was to love and admire him.

"Not one year has passed away since Doctor Keene was chosen the presiding officer of this association. The dignity and ability with which he presided over our deliberations; his amiability and courteous demeanor has endeared him to us all. He is now no more. Suddenly, and in the meridian of life, he has been called hence, and may we now hope to take a place in a better world."

"Such is the character of the men who lived just before us. Their ideal was service, which they inculcated, not only by their precept, but by their example. It is the tendency of each generation to think they do things better than their predecessors; but do we, after all? Perhaps by dwelling once in a while on the achievements and the attainments of those who came before us, we may become a little more humble and a little more eager to do at least as well as they."—William Fitch Cheney, M.D., *Reminiscences of Eminent San Francisco Physicians* (California and Western Medicine, August, 1923).

DOCTOR LAFAYETTE HOUGHTON BUNNELL,
FRONTIERSMAN

MOST of our knowledge of the life of Doctor Lafayette Houghton Bunnell we owe to his fascinating book, "Discovery of the Yosemite and The Indian War of 1851," which led to that event, and to the painstaking researches of Dr. Howard A. Kelly of Johns Hopkins, who embodied his findings in an interesting article in "The Annals of Medical History" in 1921.

Doctor Bunnell did other writing, notably magazine articles on pioneer subjects, and a book called "Winona," which is described as a mine of Indian lore.

His history reads like that of the hero of a Western novel, full of romance and adventure.

Born in Rochester, New York, November 2, 1924, the son of American parents of good English ancestry, his father a physician, his mother a member of a distinguished family by the name of Houghton, Lafayette Bunnell spent most of the formative years of his boyhood in Detroit, then a small French village. Here he saw much of Indian life and learned something of the native languages and, of course, the sign language. He vied with the Indian boys in their sports and, under the spell of the frontier tales of Dr. Douglas Houghton, distinguished naturalist and geologist, as well as physician, his mother's cousin, he was fired with the pioneer spirit of exploration and adventure.

With moderate schooling he learned something of medicine, living as he did at home in a medical atmosphere, and was employed for a time as a clerk in a drug store; but his restless spirit and his ambition to be out-of-doors led him to forsake medicine for business. As a young man he engaged in various lumbering operations in the upper Mississippi region, even rafting logs down the river to St. Louis.

He served in the Mexican War in 1847 and in 1849 it was inevitable, as Dr. Kelly puts it, with his character and training, that he should seek gold in California.

Bunnell tells the story of his having had a glimpse from a Merced trail above Ridley's Ferry of the stupendous cliff which later was named El Capitan and which, as a member of the Mariposa Battalion, he was to know and appreciate more fully when the battalion camped just across the river from this mightiest of rocks. The Mariposa Battalion was a company of hardy mining men and pioneers organized in January 18, 1851, under command of James D. Savage, a tradesman, who had great knowledge of the Indians and their ways and who was commissioned Major. This company of horsemen entered the Valley in pursuit of the Yosemite Indians who had been making depredations on the white settlements and had killed a number of pioneers. The route was that of an Indian trail, practically the now well-known and so-called 'old Mariposa Trail.' While these were the first white men to enter the Valley and were on horseback, it was known that stolen horses and cattle had been taken into the Valley by the Indians, so it was known that the trail was passable, but to those who are familiar with the snowfall of the region, the trip must have been an arduous one in March. While the expedition was not much of a success as measured by the number of

prisoners taken, it accomplished a good deal in showing the Yosemite and their foxy old Chief, Tenaya, that the settlers could not be trifled with and that the mountain stronghold and the deep valley, Ahwahne, was not a safe refuge when the whites were aroused.

While the battalion was encamped opposite El Capitan not far from Bridal Veil Falls, it was suggested that the party name the Valley, and it is to the honor of Doctor Lafayette Houghton Bunnell that he suggested the name "Yosemite," which was finally adopted. It was not the Indian name of the Valley, but the name of the Indian tribe occupying it, and signifies the grizzly bear.

Bunnell never claimed to have been individually the discoverer of Yosemite Valley, but merely to have been one of the company of white men first to enter it, and to have suggested the name. It has been established that other white men, notably the party of Joseph Walker, which had crossed the Valley on the Mono Trail to the north of the Valley, had noticed the depression and had seen and remarked on the cliffs, probably Half Dome and Glacier Point.

By reason of his knowledge of medicine, Bunnell had something of a medical or surgical outfit with him in his mining days in California, and it is to be presumed that he had occasion to assist the sick and injured. In fact, he was appointed surgeon, at least to the later expedition against the Chowchillas, and promised extra pay as surgeon.

Dr. Kelly epitomizes Bunnell's subsequent military career as follows:

"After the Mariposa Battalion was mustered out, Bunnell remained in California, trading, mining, and surveying, as late as 1856. He returned to his early home in the Middle West and on April 18, 1861, at LaCrosse, Wisconsin, enlisted in the United States Army. He was appointed hospital steward July 22, 1861, and discharged in May, 1862.

"He enlisted in 'Company B, Second Wisconsin Cavalry Volunteers, in November, 1863, and was discharged March 1, 1865, to accept a commission as assistant surgeon Thirty-sixth Wisconsin Infantry Volunteers. He became surgeon in July, 1865, and was mustered out with the regiment the same month and year.'"

After the Civil War he married Sarah Smith. They had no children. Bunnell died at Homer, Minnesota, his brother's old home, on July 21, 1903, and was buried at Woodlawn Cemetery in Winona, Minnesota.

While he was known as *Doctor* Bunnell, there has been a good deal of skepticism as to whether he had a medical diploma. Dr. Kelly, in the article cited, dispels all doubt on this matter by publishing a reproduction of the diploma granted Lafayette Houghton Bunnell by the LaCrosse Medical College in 1864, the original being now in the possession of the Minnesota Historical Society. It has further been shown that for two years, beginning at the age of 16, Lafayette Bunnell read medicine in his father's office and attended clinics, a training which might compare not unfavorably with the curricula of most American medical colleges of 1840. It is well known that in the pioneer days in California many men who achieved prominence in the practice of medicine had no great schooling and some had no diploma, and yet were honorable men.

COMMITTEE ON BUNNELL MEMORIAL,
Emmet Rixford, Chairman,
Saxton T. Pope,
Egerton Crispin.

"CHIROPRACTIC FOUNTAIN HEAD"

AN INSIDE VIEW

By A. W. MEYER, M. D., *Stanford University, California*

IT WAS not necessary to visit Davenport in order to learn that fact and fable are two different things. The advertising matter distributed freely from the Palmer School alone shows that. As everyone knows the human body, as judged by these pamphlets, is made fearfully indeed and human ills are adjusted as strangely.

I had heard "B. J." himself compare Yale with the "Chiropractic Fountain Head," in a public lecture. The implication was that the latter was rather a greater institution, and the public was told that it would soon have a dormitory large enough to house several thousand students. Unfortunately, the dimensions given for this dormitory scarcely provided comfortable standing room for this number; not even without making allowance for stairs, corridors, and partitions! In spite of these things, the speaker nevertheless was applauded rather generously, and one might have supposed that he was some long-awaited saint coming with a message for suffering humanity.

I long had wanted to see this school for myself to obtain first-hand impressions of the students, the faculty, and the equipment. "The Plant" includes a commodious old residence and four closely adjoining buildings, ranging from one to four stories in height, not including the tower. These four buildings are separated slightly from each other and are adorned with Oriental gateways, bells, totem poles, plaster Buddhas, Chinese gongs, inscriptions, and colossal plaster busts of the three Palmers. A fourth bust, of the elder Palmer, rests on a large granite base in an areaway between two buildings. It is said to be a gift of the chiropractic profession, and stands in the entrance of "Twildo," a recreation area-way, furnished with rustic seats and tables, the latter inlaid with games of various kinds.

Inscriptions are about everywhere, some of them of considerable length. One side of the brick chimney advises "Keep smiling," and the other side announces "Votes 4 Women." One end of the radio station at the rear of "Up-e-Nuf" where "Inspiration Point" is located, carries the petition, "Let George Me do it." The other end asks: "Is life worth living?" and answers: "That depends on the liver." The arch over the gateway, in front of the parkway, declares that "Anything that you do that the majority do not do is queer. Queer, isn't it."

The largest building, which bears the wireless station, is proclaimed to be eighty feet higher than the Woolworth tower. It has a roof garden and a telescope. The "printery" is claimed to be "the prettiest in America." Besides these things, the plant includes a bakery, barber-shop, cafeteria, trophy room, mailing room for propaganda, and a room adorned with photographs of 5000 actors and actresses—mainly the latter—who are said to commend chiropractic.

The same incongruousness—or even grotesqueness—evident without is present within. The hallways are full of phrases, some of which are telling, well chosen, and worthy; others queer and un-

worthy, and some are in characters only. One of the hallways contains a third colossal bust of the elder Palmer, an airplane propeller, etc.

The cafeteria was especially placarded with phrases of all kinds. One of these read: "Only a mutt can make money without advertising." The food served there was of good quality and very reasonable in price, but the place was rather untidy. The much-advertised "well" with its "old oaken bucket" yielded none of "its clear, pure, sparkling water from ninety feet below." At this I was not surprised, for in spite of its "artistic and rustic setting," it was found to be a piece of advertising like most things connected with this institution. At my request for a drink of this pure, sparkling water, the guide grinned and said that they never used it because it was unsafe, as it well might be in the heart of a large city. The cafeteria was far from being "one of the most beautiful eating houses," although I am willing to believe that it serves the students well.

The equipment of the school is composed essentially of a small series of private treatment rooms, large lecture rooms, empty save for a platform and seats, or the characteristic trapezoid steel stools; megaphones for announcements; a chart or two and, in one instance, a skeleton. Contradictorily enough, there is an x-ray room and also a separate building in which the "spinograph" apparatus is housed. Good x-ray plates maintained, no doubt, for advertising purposes, though possibly also as a safeguard, adorned the walls. Since the catalogue announces that "the chiropractor gains his knowledge as to the condition of the spine by means of his palpation," there would seem to be no need for x-rays. Yet it is claimed that "our exhibit of x-ray negatives of the spine has no equal anywhere, and nowhere in the world does another department exist that can compare favorably with our thorough and most efficient 'spinograph' department." The student is told that "the ordinary x-ray operator does not possess the skill or knowledge necessary to obtain the kind of pictures that are wanted" (!).

The "osteological studio" is asserted to be "the largest collection of abnormal specimens in the world." It is housed in glass cases in the corridors on an upper floor of the classroom building. The catalogue truly says that this collection represents years of effort, and that it affords students an unusual opportunity of study. However, it is far from being the largest collection in any except the chiropractic world. There are unusual specimens, but many of them are wrongly labeled. Some of these really are very amusing and undoubtedly a source of error to any earnest students. A tubercular specimen, for instance, is labeled "This inco-ordination is N—C. The only secretion involved is serum in transitional stages. The location involved is determined by the distribution of fibers impinged on." Sutural (Wormian) bones are labeled "Osseous tumors formed between the walls." Arachnoidal (Pachionian) depressions are taken for abnormalities. A case of ununited acromiion in an adult scapula is called an "unhealed fracture," and is said to have prevented the raising of the right arm. A myelomatous spine is called a tubercular one, and

many specimens of arthritis deformans are labeled "osteomalacia." One specimen is labeled "Nodule and depressions congenital. External deformans. Internal normal." Verily a most unusual opportunity is afforded students of chiropractic.

As stated in the catalogue, the skeletons are kept in glass cases. Among these was one, that of a male acromegallic. It was pointed out to me as the skeleton of a giantess! A rattlesnake skeleton "with 432 vertebrae" also evoked amusing comment.

The only facilities for studying anatomy, aside from those already indicated, were to be found in an Auzoux model of the entire body, which also is kept in a glass case, and a few other specimens. No dissections are done, and the lecture in anatomy revealed rather unusual functions for some of the muscles of the thigh and a unique description of fascia. This is not to be wondered at, since there was alleged to be a duct which runs from the spleen to the stomach—the "duct of Palmer." This is not surprising, since the *Chiropractic Anatomy* by Mrs. Palmer states that "Chiropractors have for the following reasons long maintained that the spleen furnishes a secretion. It is used in the process of digestion." . . . "In artificial digestions the pancreatic juice alone, or mixed with an infusion of a contracted spleen, digests nothing, or almost nothing, while the same pancreatic secretion, to which has been added the infusion of an engorged spleen, digests rapidly and copiously." It is also stated in this anatomy that "it (the spleen) has been said to be the place of origin of the ganglionic nerve cells, for it was thought to possess some mysterious influence over the mind."

Just as delectable bits of anatomical knowledge as this came from the lips of "B. J." himself in one of the "Analysis Clinics." Of these, the catalogue says: "To see this great man, the developer of this institution, and the thoroughness with which he handles cases that seem impossible of correction, is a liberal education in itself. He is a master hand at spinal analysis, and his work is most phenomenal when it is considered that his patients come from every corner of the world and are absolute strangers. Invariably they attest to the sure truth of his quick conclusions, and his analysis in each case is summed up quickly in a brief explanation to the students in attendance. . . . Here the student sees a practical demonstration of what he is taught in the classroom and, furthermore, he achieves a confidence in his knowledge of diseases and his attitude toward a sick stranger, obtainable in no other way."

In this clinic I heard from the lips of "B. J." himself that the right of a certain pair of nerves goes to the neck and the left to the stomach! Here also one learned that an old healed fracture of the spine causes a "stretching of the spinal cord with consequent reduction of its conductive capacity, just as the conductive capacity of a rubber tube is reduced by stretching." It was interesting to see how many taut fibers were in evidence in the patients brought in, and how unfailingly they were located, . . . although these cases included acute fevers, cervical adenitis, and cases of anemia.

It is unnecessary to add that the treatment of these cases not only is ridiculous, but culpable, and

it is not without significance that cripples unrelieved by chiropractic were much in evidence about the buildings. Some of these were looked upon as fixtures. In the lectures on symptomatology, the genesis of lordosis and kyphosis was explained in a most amusing way, the instructor showing not the least comprehension of pathology. In chemistry the class was asked to cross out an entire table in the text, said to be printed by the school, because it was declared to be incorrect. The lecture was on acids, bases and salts, and it was reassuring to have the guide remark: "You see, everything is made so plain that even *you* can understand it."

The students were unusually friendly, good-natured, and most of them, I am ready to believe, are quite ignorant of the sham in which they are playing a part. They now, and the public later, will pay dearly for this. Only a few seemed suspicious, and vented their indignation in no uncertain terms. However, if these had paid \$475 in advance, their position can easily be imagined.

The men in certain classes buttoned their shirts on the back and so did the women their dresses, in order to make their spines more accessible in palpation and demonstration classes, in some of which the students practice on each other. The students ranged from 18 to 60 years, and with the exception of a very small percentage, very plainly had had the advantage of but a common school education. The order was fair, even in classes numbering 250 to 300. However, some students wore red bandanna handkerchiefs about their heads during recitations. Others had baseball mitts on their hands, and still others were tickling the necks of men and women who were sitting in front of them. A few, as always and everywhere, were dozing. Considerable talking was going on while the lectures were in progress, but there was no boisterousness, not even in the hallways. Some few, apparently not all husbands and wives, or of the same sex, walked and sat with arms entwined. The attendance was taken by a proctor and classes changed every half hour, with a five-minute intermission.

The monotony of a class in orthopedy was appalling. Student after student went through a certain series of manoeuvres on the back of a prostrate fellow-student resting on two supports standing on the platform, while the instructor counted seven. Each count indicated a certain movement, and the last one the "chiropractic thrust." Large Junior and Senior treatment classes were almost wholly unsupervised. In one of the Senior classes a few patients rolled onto the floor after the thrust had been given, and one of these very evidently felt injured. Since the patient lies face downward with the abdomen unsupported, this is not surprising.

From what I had seen in print and heard myself from the mouth of "B. J." in public lectures, I had fully expected to see a far more prosperous and better equipped institution, or "plant" rather. A tuition fee of \$500 for an eighteen months' course, running consecutively, and without laboratories, should offer more if there really were something worth while to impart.

Students can enter at any time, and besides the relatively high fee, pay excessive prices for their

texts. The Palmer Chiropractic Anatomy, which is an abridged, garbled, compilation sells for \$10. It is an octavo volume of only 569 pages bound in cloth in the fourth edition, and contains many anatomical facts such as already mentioned. The quality of the paper and illustrations is good, but it should sell for about \$4. The same criticism applies to other books sold to students, especially those on the "philosophy of chiropractic," written by "B. J." himself.

One cannot refrain from quoting briefly from these volumes on philosophy, although no quotation can convey an approximate idea of their absurdity. In the introductory chapter on power it is stated that "if it takes 100 per cent of intelligence acting through 100 per cent of matter in that innate brain to appreciate beauty of the nude, you can imagine how an educated mind would look upon the same object if there was only 50 per cent of intelligence acting through 100 per cent of matter."

On page 213, in the chapter on Diseases of the Senses, it is stated that "the human race would be worse off if it were not for the number odd daily adjustments that innate adaptation unknowingly (to the educated mind) gives to us. There are very few but what get one or more adjustments every night during sleep. I refer to the acute mild subluxations. When they become chronic, that shows the inability of the internal appliforuns to handle them, and also shows that they were so excessive that they were beyond her individual help to move them comparative to the medium she has with which to work against them. The result is that while this individual is lying perfectly relaxed, there will be an attempt by innate to adjust these subluxations with these adaptive recoils, and if the subluxations is not great he will get well. While asleep there will be an internal adjunct concussion of forces going which will adjust that vertebra. These are not accidents; they are *intentional* upon the part of an adapted intelligence."

One of the ludicrous, if not reprehensible things, is the "coccygeal clinic" extended through three quarters. In the Anatomy we are told that the "segments of the coccyx have a spinal canal" and that "the nerves after passing through the inferior part of the sacrum spread out and surround the coccyx." . . . Hence, "the coccyx, like other vertebrae, may require chiropractic adjustment." It would be easy to continue these comments, but there seems little reason for further emphasis.

I cannot close this sketch without reminding my colleagues in medicine that just as long as some of them continue to refer patients to chiropractors and, in a measure, to osteopaths, instead of treating them themselves, they share responsibility for these things. The chiropractors, too, will soon begin to incorporate portions of the medical curriculum just as the osteopaths have done in the recent past and gradually extend their activities over the whole field of medical practice, retaining their sectarian designations only for their advertising value. Surely, as the Supreme Court of the United States has held, to practice chiropractic and osteopathy is to practice medicine, and it is difficult to see why more energetic steps have not been taken in the various states

to see that this vital fact is incorporated in legislation. Until that can be accomplished, let us hope that medical practitioners will increasingly realize that when they refer cases of neuralgia, neuritis, sacro-iliac diseases or neurasthenia, etc., to chiropractors and osteopaths, they are educating the public to regard these sectarians as their betters and consultants. For this folly scientific medicine and the public are paying and will pay dearly, before the public learns that all who make a profession of treating human ills should have the same minimum qualifications.

Routine Urine Examinations in University—At the University of California, a compulsory physical examination is required of all students on matriculation, according to Robert T. Legge, Berkeley, Calif. (Journal A. M. A.) The record of this examination is utilized on every occasion on which hospital or dispensary care is required, as it contains the full personal and family history and the complete physical findings. During the fall semester of 1924, 1224 men students, averaging in age from 18 to 20 years, were given complete chemical and microscopic urine examinations, and 4.2 per cent were found to have abnormal urine findings. In several of the samples submitted, two or more abnormalities were found. Of the fifty-one students whose urine specimens were regarded as abnormal, the following conditions were present: Albumin (faint trace), 34; albumin (decided trace), 6; sugar reduction, 3; mucus, 21; pus cells, 17; red cells, 4; granular casts, 4, and hyaline casts, 6. All these student cases were followed up, and it is of interest to observe the actual end-results and diagnosis. The specimens with faint traces of albumin determined in this group, in the majority of instances, were found to be physiologic, either as a result of a preliminary shower, or the escape of prostatic secretion during the excitement of the examination and the straining in the act of micturition. These cleared up on subsequent examinations. Of the six with decided traces, with or without casts, two were nephritic and one had a history of previous eruptive fevers. In three cases with red and white cells in the urine, two proved to be tuberculosis of the kidney and one a case of nephrolithiasis. The diagnosis was confirmed by cystoscopic and roentgen ray examination and animal inoculation. The patients that needed surgical treatment were referred for operation, and the remainder were treated medically. The point made is that, with the exception of one case, none of these students realized that they possessed any kidney or bladder lesions.

History of Medical Journals—"In an article written by Leartus Connor, M.D., and printed in the Journal of the American Medical Association, June 14, 1884, it is stated that the first medical journal published was issued at Paris, France, in 1679. It was edited by Nicholas de Blegny, 'who seems to have been "a good bit of a charlatan."' The first medical journal printed in the United States was in the nature of a translation of the Journal de Medicine Militaire issued in Paris from 1782-88. This appeared in New York about 1700. The first strictly American medical journal, according to Connor, was the Medical Repository, a quarterly, edited by S. L. Mitchell, Edward Miller, and E. H. Smith, and published in New York, 1797-1824. The Philadelphia Medical Museum, the second American journal, came into existence in 1804, and retired from the field after a career of seven years. This was edited by Dr. —. —. Coxe. Baltimore was the home of the third medical journal of the United States, the Baltimore Medical and Physical Recorder, 1808-09. Dr. Tobias Watkins was its editor. Medical journalism in Boston began with the New England Journal of Medicine and Surgery, 1812-27. This was a quarterly, and in 1828 was consolidated with the Boston Medical Intelligencer. This combination established the Boston Medical and Surgical Journal, which is still in existence and is now published by the Massachusetts Medical Society under the editorship of Dr. W. P. Bowers."—A. M. A. Bulletin.

EDITORIALS

MEDICAL HISTORY OF CALIFORNIA AND ELSEWHERE

The story of the beginnings, growth and development of medicine in the Golden State has never been told. This number of CALIFORNIA AND WESTERN MEDICINE is largely devoted to that subject. No attempt has been made to mold the articles into a fixed pattern, but rather to let them reflect the minds of students versed in various phases of the stimulating problem. There also are articles upon other phases of the history of medicine. We are pleased with the result, and we hope our readers will approve.

Unfortunately, several promised manuscripts came in too late to be used, and one of exceptional value had to be omitted because of its unusual length.

The complete story of the history of Western Medicine ought to be told, and the House of Delegates of the California Medical Association would render medicine and humanity a service by appointing and financing a wisely selected committee to push the work through to completion and publication.

Several of the illustrations used in this number have not before been published. Others have been lent to us by various friends and publishers. The Long Island Medical Journal and the Arlington Chemical Company, one of our advertisers, have co-operated with us most helpfully in supplying cuts of several copies of old masterpieces upon medical subjects.

We regret that biographical sketches of more of our own Western physician pioneers could not be secured.

EDITORIAL ACKNOWLEDGMENT

I wish to take this occasion to express my appreciation of the efforts of Doctor Hans Barkan, who has acted as co-editor with me in the production of this number of CALIFORNIA AND WESTERN MEDICINE.

Both Doctor Barkan and the editor wish to acknowledge the very splendid spirit of co-operation which the contributors to this number and many other physicians have shown in its production.

It would be of material assistance to the editor if readers would write notes of the reactions the number produces on them, with particular reference to whether or not in their opinion it would be considered advisable to repeat the Historical number at irregular intervals when sufficient material is available.—EDITOR.

THE PASSING OF A BELOVED PHYSICIAN

The cause of better health loses one of its most useful and valuable exponents and leaders in the passing of Walter Thomas Williamson, who died recently at his home in Portland, Oregon. All physicians everywhere lose a valued counselor, and thousands of those of Western America a loved friend. The public in general have lost a health leader of greater value to them than they will ever understand or appreciate.

DOUBTFUL METHODS OF PROMOTING PHARMACEUTICALS

Physicians always have been, and the general public is getting to be, "from Missouri" when it comes to the question of promoting new pharmaceutical and other "scientific discoveries" primarily through the public press, and particularly when there is a university's quasi endorsement behind the propaganda.

The new pharmaceutical, hexylresorcinol, may be all that the news story-writers claim for it—and it may not. Whatever is known about the drug is still in the experimental stage. To this all scientific writers whose opinion carry any great weight agree.

Detail men are pestering doctors in their offices by quite aggressive and intensive salesmanship propaganda in favor of this drug. The big talking point in this salesmanship is, that it came from Johns Hopkins University and presumably has the endorsement of that university. This we have been unable to confirm by correspondence between alumni of Johns Hopkins and the professors and heads of departments of that institution.

There is no more certain nor prompt method of destroying a worthless preparation, nor of permanently crippling the value of a good preparation, than by the "high-powered" salesmanship methods and newspaper propaganda being put forth in the interest of hexylresorcinol. Physicians everywhere resent the insult to their intelligence that they must submit to nowadays in the forceful talks so persistently presented by "detail men," some representing otherwise legitimate concerns, and others with similar methods representing those that are at best of questionable standing.

THEY KEEP THE HOME FIRES BURNING

The "home fires" are kept burning for every editor by authors on the one hand, and his editorial council on the other. Some authors, and particularly those of quite limited experience, often *resent* having their manuscripts declined; some not only resent such action, but salve their own hurt feelings by personal abuse of the editor—firewood for the home fires. On the other hand, members of the editorial council who act as confidential advisers to an editor occasionally, and quite properly, feel that he should be more discriminating than he sometimes is in what he accepts for publication. Many of these problems are interestingly analyzed in the recent autobiographies and trials and tribulations of editors by such experienced men as Stead, Mitchell, and Tooker.

Of importance in our own more restricted field are the following abstracts from letters from authors of declined manuscripts on one hand, and the confidential opinions of editorial councilors on the other hand.

One Author—"I was very angry when you declined my article on '——.' Upon reading it again after a lapse of some months, I believe you are right,

and that it would not be creditable as a part of my permanent record, nor to our Journal."

Another Author—"When I received my article back all marked up with corrections and suggestions, I was 'mad' and considered you presumptuous. After further study and a clean copy, I realize and appreciate the value of the work of the editors."

Another Author—"I am relieved that you have the impertinence to decline my article. I only sent it to help out, and will now send it to a journal with national circulation. You will not be bothered with more of my papers."

(Note—The article in question had already been declined by journals "with national circulation" before it was offered to CALIFORNIA AND WESTERN MEDICINE.)

Another Author—"Thank you for the splendid editorial work on my article on—"

Comment by members of the Editorial Council, which explains why some of these essays were declined:

One Manuscript—"I feel that this paper should not be published under any conditions. The few constructive points could be put in a brief report, omitting criticism of other authors and practitioners. We have too much destructive criticism."

Another Manuscript—"This paper has nothing to recommend it, and it would be very harmful if published."

Another Manuscript—"It is a privilege and a pleasure to co-operate with you in your splendid efforts to edit a high-grade medical journal. I feel that this manuscript contributes nothing new in its presentation and contains no attempt to compare the data with other reports in the literature. In short it is merely a case report without any effort to fix any significance to the clinical and post-mortem findings. Some value, of course, attaches to the publication of interesting case records; now and again some writer later on will collect such reports scattered in different journals and think out a story worth reading; but I doubt the advisability of publishing this manuscript in the type of journal you are editing. Your readers would not derive much stimulation from it. I am, of course, not casting any reflection on the accuracy of the reports as rendered, but the naked facts without appraisal and discussion afford but little interest to the average physician."

Another Manuscript—"I cannot see that this paper presents any material that is new or that has not been presented in far better style to our readers in the past. *It should not be published.* I do not know what your attitude is toward writers who send in papers partly typewritten and partly written by hand, full of corrections, and full of errors that need correction. Personally, I feel that if a man wants a paper published, he should send it in in such shape as he would present an essay competing for a prize, i. e., in as perfect typographical shape as he can command. In 1924 we spent over \$600 for authors' corrections. I would let the authors foot the bill."

Thus an editor is kept warm between two fires.

AMBROSE PARÉ

It was only yesterday on time's eternal calendar that physicians were arguing about whether the infection following gunshot wounds of war was caused by poison from the lead bullets or by the burned gunpowder. These wounds were treated by pouring boiling oil into them.

Then God gave to the world another great pioneer thinker and leader; one of the great surgeons of all times—Ambrose Pare. He demonstrated the startling fact when only 26 years that it was not necessary to pour boiling oil in wounds. Pare himself relates his accidental observation that men whose gunshot wounds had to be dressed with "a digestive made of the yolke of an egg, oyle of roses and turpentine" suffered less than the others dressed before the boiling oil ran out. Pare's kindliness was shown in the anxiety these patients caused him. "I could not sleep all that night, for I was troubled in minde, and the dressing of the precedent day (which I judged unfit) troubled my thoughts; and I feared that the next day I should finde them dead, or at the point of death by the poyson of the wound, whom I had not dressed with the scalding oyle. Therefore I rose early in the morning, I visited my patients, and beyond expectation, I found such as I had dressed with the digestive onely, free from vehemencie of paine, to have had good rest, and that their wounds were not inflamed, nor tymified; but on the contrary the others that were burnt with the scalding oyle were feaverish, tormented with much paine, and the parts about their wounds were swolne." Pare's shrewdness is shown by his immediate drawing the conclusion that "difficulty of curing proceeds not from the venenate quality of the wounds, nor the combustion made by the gunpowder, but the foulness of the patients bodies, and the unreasonableness of the aire."

Pare lived 900 years ago, and his memory is still green in the hearts of all lovers of the medical sciences.

Ambroise Paré

Medicine in the Public Press

A Sample of What One Newspaper Is Telling Its Readers Through an Alleged Health Column—"Why, then, is surgery so generally recommended for cancer? There are two reasons. First, it is in line with the immemorial custom of medical practice to suppress and remove symptoms, instead of going after causes, and, secondly, cancer surgery is perhaps the most lucrative branch of the profession since appendectomy declined somewhat in popularity."

Our Father in Heaven forgive them for they know not what they do.

"It's Easy to Keep Fit," says Walter Camp (Collier's) in a recent article under this title. But before the advice could be published, the author had joined those of the great beyond."

Making a fetish of exercise is no more conducive to longevity than is plowing corn or hoeing potatoes.

Which Is Equivalent to Saying What?—Doctor Alexis Carrel is quoted as saying that "the development of a new psychology is our only hope of improving the quality of human beings."

"Health First"—In a column under this heading, we read in the San Francisco Daily News that "It is an authentic fact, which no medical denial or camouflaging can wipe out, that in the 'flu' epidemic of 1918-19, every drugless healing cult in the business proved itself more efficient in caring for their patients—and with a lower mortality rate—than the regular medical school."

Itinerant Psychologists in Action—Another of these recently completed a series of "free" lectures in San Francisco. According to a newspaper this "erudite healer" made quite a hit with two large charts which "prove conclusively that two people with protruding chins shouldn't marry. When they kiss, their chins will strike, and then look out for the fireworks! Two people with long noses shouldn't mate—their beaks will get all messed up with each other."

How Big Medicine Works—In the recently published letters of Franklin K. Lane, that distinguished Californian telling of his experiences at a large clinic says:

"I am being ground and wound and twisted and fed into and out of the Mayo mill, and a great mill it is. Of course, they are giving me a private view, so to speak. Distinguished consideration is a modest word for the way in which I am treated—not because of my worth, but because of my friends. Those men are greater as organizers, I believe, than as workmen, which is saying much indeed, for they are the surgeons supreme. . . . Two or three hundred people, new people, a day pass through (their shop). Sixty to seventy thousand a year received, examined, diagnosed, treated perhaps, operated on (50 per cent) and cared for. The machinery for this is colossal and superbly arranged.

"Dr. Mayo told me to come over at 2 o'clock and register. . . . I stood in line and was duly registered, telling name and other such facts, non-medical. Then a special guide took me to Dr. Mayo, who had already heard my story at the hotel but who wished it in writing. Accordingly, I was presented to a group of the staff and one man assigned as my escort. I answered him a thousand questions, touching my physical life for fifty-six years. Then to the tonsil man, who saw a different 'focus,' now and there, a focus in the tonsils! Nose and ears without focus or focii or focuses. Down an elevator, through a labyrinth of halls, down an inclined plane, up a flight of steps, two turns to the left, and then a group of the grumpiest girls I ever saw or heard or felt. They were good looking, too, but they didn't care to win favor

with mere males. They had a higher purpose, no doubt. They openly sneered at my doctor escort. They lifted their eyebrows at my good-looking young son, and they told me precisely where to sit down. I was not spoken to further. My ear was punched and blood was taken in tubes and on slides by young ladies who did not care how much of my blood they spilled or extracted. They were so businesslike, so mechanical, so dehumanized, these young ladies with microscopes! One said cryptically '57,' another said '53.' I was full of curiosity, but I did not ask a question. They tapped me as if I were a spring—a fountain filled with blood—and gave me neither information, gaiety nor entertainment in exchange. Each one I am convinced has by this life of near-crime, which she pursues for a living, become capable of actual murder.

"There are 150 physicians and surgeons in the clinic, and Heaven knows how many hundred employees. No hospitals are owned and run by the Mayos; all these are private, outside affairs. The side tracks are filled with private cars of the wealthy. Scores of residences, large, small, fine and shabby, are little hospitals.

"I am tomorrow to be medically examined further, to the revealing of my terrible past, my perturbed present, and pacific future. The result of which necromancy I shall duly report. I am afraid that they will not find that an operation will do good; if so I shall truly despair. And if they decide for the knife, I shall go to the guillotine like the gayest Marquis of the ancient regime. Yes, I should do better, for I have my chance, and he, poor chap, had none."

Old Maids and Evolution—Haeckel, who followed and extended Darwin's conclusions about evolution and heredity, believed that it was not necessary to be a parent to become an influence in this field. He recognized "indirect adaption," which he jokingly illustrated by this story:

"The superiority of Englishmen is due to their being fed on excellent beef; but the beef results from the cattle being grazed on rich clover pastures. Clover is fertilized by wild bees, but wild bees are decimated by field mice which are being kept in check by cats. Cats are usually kept by old maids and, therefore, this habit of unmarried females is the original cause of British pre-eminence."

More "Health Education"—A San Francisco newspaper through its "Health First" column says: "The public school child, in particular, is looked upon as fair game for medical exploitation; and through the officious activities of 'medical inspectors' and 'visiting nurses' this most helpless and dependent class of society—the new-born hope of races—are vaccinated, Schick-tested, serumized and 'immunized'; poisoned, crippled, syphilized, and mutilated, in the name of 'science'!"

A Compliment to the Stimulating Effects of California Climate—A "noted medical authority" who told the newspapers that he came West to confer with Governor Richardson about establishing a "psychopathic ward in San Quentin" also gave some glad tidings to the doctors of the wild and woolly West when he exonerated pie, plum pudding, and Welsh rarebit from responsibility for bad dreams. He says that it's all a matter of the "subconscious mind."

Surgeons Classed With Highwaymen—The "health column" of a San Francisco newspaper says of surgeons: "The highwayman of the Jesse James type demands: 'Your money or your life.' The modern surgeon takes both. For even where death does not immediately ensue, the mutilated victim is condemned to a living death of misery oftentimes."

Are Garterless Socks a Health Menace?—One of our good doctors is quoted in the press as saying that: "Flopping socks leaves the delicate ankles exposed to the inclemencies of the weather. This brings on not only

colds, but a general loss of vitality and weakening of the collegians' robust constitutions."

The statement doesn't sound like what the doctor would have said, but in any event it furnished "copy."

"The New Hokum"—"When I was quite a small boy," says Wallace Irwin (Collier's), "I used to think that the Greek word Psyche was pronounced 'fish,' and, although I soon learned my grievous error, in my years of experience I am beginning to believe that children are sometimes intuitively right. In these later years they have twisted Psyche into psycho—psycho-this, psycho-that—until the saner of us enjoy a keen sense of fishiness even while we incline our ears to fish stories clothed in more or less scientific nomenclature . . . Inhibitions, Complexes or Repressed Personalities. If you get these three catch-words in your head, you can go far in psychoanalysis. Inhibitions, Complexes, Repressed Personalities—you have practically the whole conjuring kit.

". . . Between amateur child culture and home-brewed psychoanalysis, I often wonder what the next generation is going to be like.

". . . Psychoanalysis, of course, is getting a little stale in America, where it hit rather late. Like cubism and mah-jongg, it is bound to be replaced by some newer, sillier caprice. Already the cubists are being regarded as quaint fogies, and the cross-word puzzlist—himself doomed to extinction—jeers at Grandpa and his Chinese tiles."

Some Things That Are Called Medical Education—A doctor revives an old controversy by saying that:

"The blonde is more irresponsible, nervous and flighty; she doesn't sit down and take life seriously, she is usually frail, and liable to get into trouble much more easily than a brunette." He adds in even more general terms that the "darker type of person is calmer, more settled, and uses better judgment in most cases than the fair-haired species."

Suppose this is a fact—which it isn't—what of it?

More Health Education!—"A learned doctor" is quoted as saying that: "Smoking alters women's faces, making their features sharper and their skin taut. The corners of the lips become prematurely wrinkled and there is a tendency for the lower lip to project past the upper. The eye of the female smoker also undergoes a change. The lids move more slowly and some of them even become cross-eyed."

These claims are not new as propaganda by the anti-tobacco crowd, but they rarely are able to induce "a learned doctor" to endorse their claims.

Not So Simple—The question of drug sickness is neither so insignificant nor limited among our citizens as the San Francisco Bulletin (editorially) makes it out to be. In condemning the drug addict hospital bill now before the legislature, the editorial in question says:

"Money is to be taken from those that have earned it, and spent on those that, instead of earning anything, have devoted their time to making wreckage of their lives. Prudence and frugality and thrift are to be penalized for the benefit of fools."

If the benefits of medical science were to be withheld from all whose troubles are due to ignorance or folly, the state could still further reduce its expenses by many millions. The statement in the editorial that:

"There are some drug addicts that have become addicts through the misfortune of disease and pain, but they are very few, and usually get over it when the occasion passes, or cure themselves by an exertion of the will. They need no legislation."

Such statements reflect an ignorance of narcotic disease that is surprising.

"When Doctors Disagree"—Under this heading the San Francisco Daily News says editorially:

"The century-old conundrum which has puzzled the

lay world since the dawn of medicine, now confronts the newly impaneled jury in the Dorothy Ellingson case that is to decide the question of the girl's sanity.

"Two eminent alienists, psychiatrists, psycho-analysts—and whatever other expert terms may add to the weight of their authority—called in to pass judgment on the 16-year old matricide's mental condition, are in absolute disagreement about it.

"Dr. Jau Don Ball, employed by the defense, after probing into Dorothy's psychic anatomy and watching her during a tantrum, announces to the court that the prisoner is suffering from 'psychosis' and stakes his professional reputation on the die.

"On the other hand, Dr. Joseph Catton, chief of the prosecution's staff of alienists, stands by his original judgment that the girl is normal in every way.

"And now the jurors will have the double task of deciding not only the sanity of the jazz girl, but of the doctors!"

Is It a Man's Gifts or His Training?—"One of the dangers of an advancing civilization going forward through the mechanism of an education process is that it opens the door to so many various activities as to endanger the social homogeneity of that civilization. Human beings are not equal and never can be, either individually or racially. The notion that they are so or may be so is no more than a dream of humanitarian sentimentalists.

In the fashion of the world of trade it dispenses the capabilities of the richly endowed and so changes the poverty of the common man into what seems like affluence. The pioneers who made America and turned its original ugliness into beauty have been followed by a host of lesser folk eager to eat at our table. In popular education a like thing happens.

If we cannot attend to the mediocrities and at the same time do the best for the best, we should let the mediocrities go. Education at the higher levels is for leadership, for initiative, for inventive achievement. Even in a democracy not all can lead. . . . It is time to stand at the door of the college and the university and thin the mob on its way to the seats of honor. This very thing is now being done in America."—Lewis Worthington Smith (Dearborn Independent).

What About These Law Violators?—Californians are daily being treated to an interesting line of disregard for law by so-called "herbalogists."

These unlicensed "doctors" not only carry extensive advertisements in the public press, but give their office hours and make such claims as these:

"Come and have us give you a scientific diagnosis that will tell you absolutely the true condition of your whole system."

"No matter what your affliction is, come and be made well again by the herbs God put in the ground for the very purpose of healing mankind: we guarantee to relieve all ailments."

"We have restored sufferers to health who had been given up. They came to us as a last resort and were made well by the wonderful Chinese herbs."

"We have herbs which will give you permanent results for gall-stones, asthma, goiter, stomach and liver trouble, weak kidneys, rheumatism, constipation, heart trouble, diabetes, high blood pressure and general tonic to build up your run-down condition."

"Our wonderful Chinese herbs offer relief for the stomach, kidneys, nerves, skin and rheumatism and indigestion, hemorrhoids."

If this isn't flagrant disregard for law, what is it? Why are these law violators not punished?

For most men torment themselves with watchings, journeyings, and running up and down for no advantage and with no good design, but only that they may do others an injury, or because they envy them or are competitors with them, or because they hunt after unprofitable and empty glory. To such as these I think Democritus chiefly spoke, when he said, that if the body should summon the soul before a court on an action for ill-treatment, the soul would lose the case. And perhaps, on the other hand, Theophrastus spoke well when he said, metaphorically, that the soul pays a dear house-rent to its landlord, the body.—Plutarch's Rules of Health.

WAHRHEIT UND DICHUNG ANENT

THE SACRAMENTO SOCIETY FOR MEDICAL IMPROVEMENT

By WALLACE A. BRIGGS, M. D., *Sacramento*

The Sacramento Society for Medical Improvement, organized March 17, 1868, has the undisputed distinction of being the oldest, in continuous existence, of all the medical societies of California. Of its twenty charter members, eight or ten were physicians of exceptional ability, attainments, and service. In the order of their registration, these were:

Thomas M. Logan, who first began systematic meteorological observations in the state and was, I believe, the first secretary of the California State Board of Health.

F. W. Hatch, a scholarly gentleman of Virginian lineage and education; frequent contributor to the medical journals of the time and, for many years efficient secretary of the State Board of Health.

G. L. Simmons, prime mover in the organization of this society, to which he gave its present name, of which he was the most devoted member and, until his fatal illness, its most faithful attendant; the best of our early surgeons; author of numerous papers on medical and surgical subjects; founder and, for many years, chief supporter of the first hospital of Sacramento, the lineal predecessor of the present Sisters' Hospital; one-time president of the State Society.

G. G. Tyrrell, redoubtable democrat; author of many medical papers; secretary of the State Board of Health; permanent secretary of the State Society and later, I believe, its president.

W. R. Cluness, genial family physician; master of obstetrics, who, in the room next the wailing patient, could calmly sleep, wisely avoiding "meddlesome midwifery" by letting nature take its course until the physiologic—not always with the patient, however, the "psychologic"—moment had arrived; one of the founders of the Pacific Mutual Life Insurance Company and long its medical director, laboring for many years to collect life insurance statistics which were consumed at last in the San Francisco catastrophe which the local citizens of that city by the sea call a fire, and recalcitrant insurance companies denominated an earthquake—the tragedy of his life; generous friend of young and struggling confreres and popular president of the State Society.

Edward R. Taylor, scholar, poet, and that noblest work of God, who, later, became mayor of our wayward metropolis.

H. W. Harkness, scientist of no mean pretensions, nipped a little in the bud by the untimely frost of wealth.

W. T. Wyte, botanist and microscopist, and later Professor of Materia Medica, I think, in Cooper Medical College; and last but, in picturesque personality, not least, a year or two later, H. W. Nelson, audacious surgeon, bon viveur, who, at the society's banquets, drained his cups not always "wisely, but too well" and trailed his serpentine mustachios over his ears and down his back to prevent their unseemly swimming in the soup—a galaxy of stars of various magnitude, brilliance and idiosyncrasy, unequaled by any other county or municipal medical society of its numbers, within my knowledge—now all, including the Nelsonian asteroid, returned to dust—star-dust.

The baptismal paper of the society, entitled "What Connection Exists Between Erysipelas, Diphtheria and Scarlet Fever," espoused the thesis of their consanguinity and suggested that, if the patient survived the initial shock of either disease, the ultimate diagnosis might depend on the prevailing epidemic influence. Dr. Fin de Siecle, forego thy condescending smile: what may the better part of a century do to thy fine-spun theories of gossamer. And haven't we just discovered the near affinity of erysipelas and scarlet fever more than fifty years behind Dr. Frey? But, like other prophets, Dr. Frey was without honor in his own country. His ingenious theory was vigorously assailed and the doctor himself soon retired to the obscurity of a suburb of the metropolis.

Two weeks later Dr. Catman read a paper on "The Treatment of Typhoid Fever," in which, as reported, he maintained that the cause of this scourge "could be found

in an intense and protracted action of the nervous system, whereby melancholy and great depression are produced." This seems to us not unlike a whiff from Tutankhamen, but, of the members present, only Drs. Simmons and Tyrrell appear to have held their noses. Two weeks later, again Dr. Cluness read a paper on "The Use and Abuse of Alcohol," which, after the lapse of nearly sixty years, is not an anachronism. At the next meeting, Dr. Harkness read a really scientific paper, based on original research and buttressed by actual thinking. Unfortunately, at the close he ventured into the treacherous realm of prophecy and, himself a microscopist, relegated the solution of the etiology of malarial fever to the chemist! The next paper, entitled "Scarifying the Gums and Death Therefrom," was read by Dr. Hatch, who reported four deaths following that simple procedure. It was a fact significant to Dr. Hatch that, in all of these cases, mercury had been used more or less persistently.

In its lusty infancy the society met twice a month, and its feasts, judging by the record, were intellectual rather than gastronomic, and its appetite seems to have been insatiable, for, with a membership of twenty, there was a formal paper at each meeting. There were evidently intellectual gourmards in those days. But the intellectual fecundity of the society seems to be in inverse geometric ratio to its numbers. With five times the membership today, it averages about one-third as many papers—less than 10 per cent of the original output per capita. The question not unnaturally arises, Is contraception at work, or is it a case for Steinach?

Meanwhile, between its precocious infancy of perpetual motion, when every movement was a joy and every new sensation an ecstasy, and its seeming post-climacteric of inhibited if not atrophic thyroid, pituitary and gonads, the Sacramento Society for Medical Improvement has served the profession and the public, on the whole, not unfaithfully, and it has contributed its share at least to that progress which, by a witty Frenchman, has been defined as a sentiment in contra-distinction to evolution which is a fact. Notwithstanding the opposition of a few, it has been in common with the profession at large, a contributing delinquent to the ignominy of our present medical law, whose noxious and unexpected by-products are the multiplication of imbecilities raised to the doubtful dignity of legalized medicine; an inevitable confusion of the public mind regarding scientific medicine which the latest fledgling of the medical law can properly toast as "Once our superior, now our equal"; an increasing socialization of medicine and the substitution of the judgment of majorities or of concubinal minorities, for individual judgment, in matters of chiefly personal concern and the consequent atrophy of that individual judgment now being reflected in majority judgments, that is, in government itself. In these matters vox populi vox diaboli.

Not only did we beget this medical law which, like that monster of fable, has turned upon its creator, but in the dim backward and abysm of time we attempted the fatuity of its enforcement. A horny-handed cyclops, by trade a blacksmith, by profession an "eye doctor," who having one eye, knew, of course, how to save the other, for not only had he saved it, as you could plainly see, but he had saved many another, as was proved by voluminous testimony and the actual presence of the eyes in court. A jury of his peers upheld the good old Anglo-Saxon doctrine of the inalienable right of every man to live or die or to save or to lose an eye at the hand of whatever doctor he likes. And this is Nature's edict—inspired and eternal.

Worth Meditating Over—"What is the element which enables some physicians to hold the confidence of their patients," asks the New York State Journal of Medicine editorially. "Think over the names of your personal friends who are highly successful general practitioners of medicine. What do they do that is different from the methods of their confreres? . . . Frank Billings states that: 'I made a point never to take more than four new patients in any one day in my office. I saw some patients daily who had been to me before, but I wanted plenty of time to go thoroughly over new patients. I had always been struck by the fact that patients who stripped sometimes did it reluctantly and often made a remark that they had never been unclothed for examination before.'"

HISTORY OF THE COUNTY MEDICAL SOCIETIES OF SOUTHERN CALIFORNIA

Compiled by William Wenzlick, M. D., Los Angeles

NOTE—*Doctor Wenzlick has compiled a very complete history of the medical profession of Southern California, from which these notes are abstracted. It is hoped that the complete history will be published later.*

LOS ANGELES COUNTY

1871, January 25—There were six physicians present in the office of Dr. H. S. Orme. A constitution and by-laws were drawn up January 31 at the office of Doctors Griffin and Widney. Seven charter members signed the constitution on February 7, 1871, and thereby created the Medical Association. There were: John S. Griffin, Henry S. Orme, Joseph P. Whitney, William F. Edgar, R. T. Hayes, L. L. Dorr, and F. H. Rose. Officers for the first year were: John S. Griffin, president; L. L. Dorr, secretary. There were no officers from 1872 to 1876.

1876, April 4—The society endorsed the bill for the Regulation of Medicine, which became a law April 3, 1876, and was amended April 1, 1878. February 1—A communication to the City Council was drawn up showing the unsanitary condition of the city and urging the establishment of a board of health and appointment of a health officer. At the request of the Council, the society on June 1 elected Dr. J. H. McKee for the position. June 4, there was a general discussion on the peculiarities of malarial fever as manifested in this locality, and upon the anti-malarial virtues of the eucalyptus tree.

1877, February 6—A motion was carried to report irregular practitioners to the district attorney. A committee on ethics was appointed, and the newspapers were requested not to publish any names of the profession in connection with accidents, surgical operations, or private professional matter.

1878, July 3—The society was incorporated under the name of "Los Angeles County Medical Association."

1884, August 1—Arrangements were begun for the organization of the Southern California Medical Society.

1888, August 2—A special meeting was held to suppress quackery.

1896—A more intimate affiliation between the State Medical Society and its county units was proposed and carried.

1910—The Los Angeles County Society had a membership of over 400 this year. The bulletin of the society has become an historical record of the society's transactions and, incidentally, also of the general medical progress in Southern California.

1912—This society is the largest county unit in California, with 568 members versus 557 of San Francisco County. This shows that medical societies, as well as other activities in this indivisible Golden State, help in the general progress of California.

1918—The secretary-treasurer, George H. Kress, M. D., incumbent since 1910, completed his seventeenth year of service, and announced that his work would end with this year. During his term the society had grown step by step from a modest and simple beginning to an organization which included all the many professional activities systematized in perfect order for the effective progress of medical science. The Medical Officers' Reserve Corps of the Army and Navy; the Medical Corps of the National Guards, 18,000 strong, of whom 8500 applied for commissions, and the League for the Conservation of Public Health, were fostered by Doctor Kress.

1919—The society presented a set of resolutions and gave a token of esteem in the shape of a watch to the retiring secretary, Doctor Kress. Doctor Harlan Shoemaker succeeded him. He worthily follows with like ideals for the good of the order.

1921—The fiftieth anniversary of the Los Angeles County Medical Association was celebrated at the Ambassador Hotel, in honor of the founders of the society.

1925—The directory of 1924 of the Board of Medical Examiners shows that Los Angeles County has a total of 2935 licentiates, of which 2730 are physicians and surgeons. And on October 16, 1924, the membership of the Los Angeles County Medical Association was 1429. The

growth of the society, from seven members in 1871 to this number, has been conspicuous in an ever-increasing ratio. Its members individually and collectively are doing their professional and their civic duty in a conscientious and efficient manner *pro bono publico*.

ORANGE COUNTY

In June, 1889, Los Angeles County was divided at Coyote Creek, the smaller southeast segment becoming Orange County. Immediately thereafter, June 13, the Orange County Medical Association was organized through the efforts of C. D. Ball and J. A. Crane. The charter members were W. B. Wall, J. A. Crane, J. M. Lacy, C. D. Ball, J. P. Boyd, J. L. Dryer, S. B. Davis, J. R. Medlock, L. H. Fuller, J. H. Bullard, W. B. Wood. The next meeting was held June 25, at which time a constitution and by-laws were adopted, and under the permanent organization the following officers were elected and installed to serve until the first annual meeting in 1890: President, W. B. Wall; vice-president, J. M. Lacy; treasurer, W. B. Wood; secretary, J. P. Boyd. Board of Censors: C. D. Ball, J. R. Medlock, J. H. Bullard. The first paper was read by C. D. Ball at the meeting of July 2, who reported some interesting cases of pulmonary disease. From 1890 to 1925 the society has steadily progressed in membership. A new generation has replaced the organizers. Only two of the pioneers remain. The new members are carrying on and are now meeting the conditions as they arise.

IMPERIAL COUNTY

Not many years ago a barren desert where men died from lack of water, will soon become a paradise more populous and prosperous than ever were the irrigated valleys of the Nile. The Boulder Dam will never fail to furnish the Colorado River water without stint and make the alluvial soil produce abundantly the food we need.

These are Imperial County's pioneer days. Things are in the making. Medical history there, it is true, has only just begun, but the founders have organized a county society, and we miss its story of stern facts which the officers have not yet compiled for us.

RIVERSIDE COUNTY

The Riverside County Medical Society was founded May 13, 1893, the charter members being C. J. Gill, J. C. Baird, M. Maybee, D. B. Rutherford, E. S. Goodhue, F. M. Gardner, L. W. Gardner, G. G. Kyle, W. B. Sawyer, A. A. Sulzer, Frank H. Moss, F. B. Morrell, C. W. Craver, R. D. Barker, T. E. Ellis, W. B. Payton, W. F. Perry, C. S. Dickson, J. L. Shibley, C. E. Lawrence. There have been no other medical organizations in this county. Some of the most important progress in our county has been the formation and development of the County Society, which has stood for the better things medically, and at the present time there is a splendid esprit de corps.

SAN BERNARDINO COUNTY

According to the "Medical Profession of Southern California," Dr. George H. Kress, editor, this society was organized June 7, 1902, at a meeting of the regular physicians of San Bernardino County, which met in San Bernardino and organized by electing J. P. Booth of Needles, president; Hoell Tyler, vice-president, J. M. Hurley, second vice-president, C. O. Mackechnie, secretary-treasurer.

The society was organized with a membership of sixteen, and meetings were held in San Bernardino monthly.

SAN DIEGO COUNTY

The San Diego County Medical Society was first founded July 26, 1870. Its founders were H. B. Hoffman, president; Jacob Allen, vice-president; T. C. Stockton, secretary-treasurer; and Robert Gregg.

In July, 1886, the society was reorganized, but no meetings were held. December 1, 1886, the present society was organized, with Dr. McSwegan as president, C. C. Valle, vice-president, and D. B. Northrup as secretary.

SAN LUIS OBISPO COUNTY

Dr. Kress, in his Medical History, 1910, says:

"The San Luis Obispo Medical Association was founded September 29, 1892. It was first known in 1892 as the

'S. L. O. and Northern Santa Barbara County Medical Association.'

"The names of the founders were as follows: W. W. Hays, president; G. B. Nichols, vice-president. S. M. Hitt, secretary; J. N. Conley, treasurer; H. C. Murphy, H. C. Bagley, C. C. Gleaves, J. H. Gass."

SANTA BARBARA COUNTY

The Santa Barbara County Medical Society was founded July 4, 1894. The founders were Doctors Anderson, Bates, Hall, MacKinley, Parks, Stoddard, Sidebotham, and Shaw. Doctor Shaw was the first president. The society has had the usual history of such organizations in small cities, until at the present time it numbers about fifty-six members in good standing.

The hospital history begins in 1891, before which time there was no regular building; a band of devoted women procured or erected a building to be known as the Cottage Hospital, with Richard J. Hall as its first surgeon.

VENTURA COUNTY

Dr. F. E. Blaisdell, Jr., president of the society writes:

"In May, 1886, there were four licensed physicians in Ventura County: Drs. C. L. Bard, A. J. Comstock, R. W. Hill, and O. V. Sessions. From these pioneer physicians, the sparse population of a large territory received a willing and skilful service. In the early days, down to about thirty years ago, the horse and saddle was the most practical, quickest, and safest means of travel for the doctor.

"Following the building of the Southern Pacific Railroad in 1886 and 1887, the population rapidly increased, and more physicians came.

"On March 25, 1890, the first County Medical Society was organized, all the physicians of the county participating. The charter members were Drs. Cephas L. Bard, A. J. Comstock, R. W. Hill, J. P. Hinckley, A. L. Kelsey, Joshua Marks, D. W. Mott, C. F. Miller, M. F. Patten, B. L. Saeger, O. V. Sessions. The first officers were: Dr. C. L. Bard, president; Dr. D. W. Scott, vice-president; Dr. A. J. Comstock, secretary. These physicians met monthly to exchange views and experiences upon the most advanced phases of medical practice.

"Those who have passed to their reward, Drs. C. L. Bard, A. J. Comstock, M. F. Patten, John Love, F. H. Huning, are remembered by the living in tenderest appreciation for their skill and devotion.

"From the coming of the first white settlers down to the present time, it is conceded by the profession and the laity that, for length of service, hard work done under pioneer difficulties, and for the impress of gratitude and affection left upon the hearts of the county's entire population, the life work of the late Cephas L. Bard stands highest in the medical history of Ventura County.

"In 1917 the membership of the Medical Society consisted of twenty-five members, consisting of the addition of Drs. J. C. Strong, G. S. Herbert, Allen Peek, A. A. Maulhardt, C. A. Jensen, T. E. Cunnane, G. H. Stockwell, Peter Cavanagh, Philo Hull, Benjamin E. Merrill, W. R. Livingston, Ralph W. Avery, Benjamin F. Korts, Charles Teubner, W. J. Lewis, R. W. Homer, John Crawford, Will R. Manning, Grace H. Sharp, Harold B. Osborne, Phillip S. Van Patten, J. T. Gardner. The society prospered and was very active until the World War interrupted.

"Since 1917, the society has had a hard struggle. The older members lost interest or found that their health prevented their attendance at the meetings. The society was kept alive only by persistent efforts of the younger and more recent members. However, during the past couple of years the comparatively few active men of the society have made the monthly meetings regular and well worth while, so that once again the society, small it is true, is again coming to the front and is a real live organization. Speakers from Los Angeles, Santa Barbara, or more distant points are always willing to come and talk before the society, and thereby increase our knowledge and keep us in intimate touch with the advances of the medical and surgical profession.

"There are at present sixteen active members, as listed in the directory of 1924. This is the smaller half of the thirteen active physicians of the county."

HISTORY OF THE ALAMEDA COUNTY MEDICAL ASSOCIATION

By PAULINE S. NUSBAUMER, *Secretary*

The following may be of *Historical* interest: Minutes of the Alameda County Medical Society, August, 1860.

San Leandro, Alameda County, August 18, 1860.

At a meeting of physicians of Alameda County held at the Court House, San Leandro, August 18, at 2 o'clock p. m., there were present Drs. Haile, H. Gibbons, Green, Randall, Coleman, Newcomb, and Worthington.

On motion of Dr. Gibbons, Dr. Haile of Alameda was chosen temporary chairman and Dr. Worthington of Oakland temporary secretary of the meeting.

Dr. Newcomb then moved "that we now proceed to organize a county medical society," which motion was carried. Dr. Newcomb moved that a committee of three be appointed by the Chair who shall draft a Constitution and By-Laws for the government and regulation of this society, and report same at next meeting. Carried. Whereupon the Chair appointed Drs. Newcomb, Gibbons and Worthington as said committee. After some discussion in regard to credentials and qualifications for membership, Gibbons moved "that when we adjourn, we do so to meet at this place for the purpose of permanent organization and examination of credentials for membership. Carried. Gibbons then moved that when we adjourn, we do so to meet at this place on Saturday next (25) at 2 p. m. Carried. Randall moved that secretary be requested to inform other physicians of the county, *not now* present, of the next meeting. Carried.

The chairman then declared this meeting adjourned.

(Signed) R. WORTHINGTON,
Secretary pro tem.

HISTORY OF THE MONTEREY COUNTY MEDICAL SOCIETY

By T. C. EDWARDS

Forty years ago there were but nine physicians in Monterey County outside of Monterey City. One of these kept a drug store and did not engage in the practice of his profession. Another was the "county doctor" and did little outside work. Of the others, two were located in Salinas, one in Gonzales, and one in Soledad, while there was none between Soledad and the San Luis Obispo County line. At this time there is no record so far as known of more than four or five practicing physicians at Monterey. Twenty years later there were nine in Salinas, seven in Monterey, thirteen in Pacific Grove, one at Gonzales, and two each at Soledad and King City, one in San Lucas, and one in Bradley, making thirty-six in all.

Some twenty-five years ago the physicians of Santa Cruz, San Benito, and Monterey Counties, organized what was called the Tri-County Medical Society. "Our own" Saxton Pope and his "Better Half" or Dr. Emma, as we familiarly called her, were shining lights in this society. The meetings were held alternately in the different counties, and were well attended, good papers were read, and an active interest was maintained. About this time, Dr. McCormick came out from Kentucky, under the auspices of the American Medical Association, and preached the novel doctrine of good fellowship, harmony, and co-operation among the members of the medical profession. To his efforts, coupled with the very able and active help of Dr. Jones, we may attribute much of the present strength and activity of the California Medical Association.

Following quickly on the heels of this campaign for common sense and common courtesy, Philip Mills Jones used his good offices, to the end that a county society was organized here and the following were the first officers, viz.: President, John Parker, M. D., Salinas; vice-president, E. K. Abbott, M. D., Monterey; secretary, N. E. Richardson, M. D., Salinas; treasurer, Doris Brumwell, M. D., King City. Censors: Drs. E. J. Rankin, Gonzales; H. B. Christensen, Salinas; and A. M. Ritchie, King City. Alternate: Dr. T. C. Edwards, Salinas; second alternate: N. E. Richardson, M. D., Salinas. Now there are thirty-six physicians in the county and twenty-two members of the County Medical Society.

The meetings of the Monterey County Medical Society are well attended, considering the distance over which

the twenty-two members are scattered, and the long drives required to attend. We have recently listened to some very interesting and helpful papers from our colleagues in San Francisco who have been kind enough to give us their time. At our last meeting in April, W. M. Gratiot of Monterey presented a most interesting and enlightening paper on "Cancer," which was discussed by the other members of the society.

HISTORY OF THE SHASTA COUNTY MEDICAL SOCIETY

By C. A. MUELLER, *Secretary*

The Shasta County Medical Society was organized by a representative of the State Medical Society, on September 20, 1903. A committee on organization was appointed to select a constitution and by-laws in conformity with the constitution and by-laws of the medical society of the state of California.

The original membership of Shasta County Medical Society was: O. J. Lawry, president; J. M. Read, vice-president; R. F. Wallace, secretary. C. W. Harper, treasurer; B. E. Stevenson, C. W. Bryant, L. J. Tabler, trustees; A. B. Gilliland, J. M. Read, C. W. Bryant, executive committee. Other members: E. H. Pitts, M. D. Pratt, D. B. Fields, J. E. Taylor, J. H. Foothill, Thomas J. Edgecomb, T. H. Shanks.

COUNTY NEWS

CHANGES IN MEMBERSHIP

New Members—Alameda County—Omer R. Etter, E. Geoffrey Smith, Charles C. Boericke, Oakland.

Contra Costa County—Rosa A. Powell, Richmond.

Fresno County—Oliver P. Pisor, Monmouth.

Imperial County—Philip Hodgkin, El Centro; Alfred L. Heck, William T. Talbott, Brawley; Ralph M. Smith, Calexico.

Los Angeles County—Henry S. Keyes, William Noble Carter, Walter Christensen, A. E. Hoffman, George S. Kalichman, William P. Kroger, William C. Lucas, W. F. McCool, John P. Mortensen, Newton M. Otis, Emmet A. Pearson, David R. Robbins, Emmason A. Rose, William Benbow Thompson, John G. Turley, Calvin B. Witter, William A. Key, Los Angeles; William Cole, Suttan H. Groff, Charles S. Means, Long Beach; William Edler, Pasadena; Archibald C. Weaver, Santa Monica.

Mendocino County—R. O. Le Baron, Talmage; Royal Scudder, Fort Bragg.

Orange County—John D. Ball, J. Muncey Bulpitt, Z. N. Bulpitt, Franklin H. Gobar, M. L. Pindell, Santa Ana; G. I. Sellon, Fullerton.

Riverside County—Leslie J. Clark, Hemet.

Sacramento County—Herbert S. Burden, Richard Gray Soutar, Sacramento.

San Benito County—Lloyd E. Smith, Hollister.

San Bernardino County—Gordon I. Reynolds, Carl Williams, Ethel H. Williams, Loma Linda.

San Diego County—C. E. Strite, La Mesa; Donald K. Woods, Frederick L. Schwartz, San Diego.

San Francisco County—Norman N. Epstein, D. G. Macpherson, San Francisco.

San Joaquin County—James F. Doughty, John A. Smither, G. L. La Berge, Tracy; C. A. Broaddus, Fred Foard, Stockton.

San Luis Obispo County—Paul K. Jackson.

Santa Clara County—Dudley Fagerstrom, San Jose; Louis Mendelssohn, Saratoga.

Santa Cruz County—Harold J. Beaver, Santa Cruz.

Siskiyou County—Joseph D. Mahan, Fort Jones.

Sonoma County—H. K. Wilson, Healdsburg; John L. Spear, Lyde H. Bernard, P. S. Quarry, Santa Rosa; G. W. Burgess, Guerneville.

Yolo County—E. Eric Larson, Walter J. Spencer, Woodland.

Transferred Members—Richard G. Scribner, from Yuba-Sutter County to Sacramento County; Frank H. Paterson, from Santa Clara County to Orange County; John C. Hethcock, from Orange County to Santa Cruz County; Emil Windmueller, from Los Angeles County to Sacramento County; Emil L. Cottrell, from Humboldt County to Santa Clara County.

Resigned—Susan J. Fenton, Oakland; Joseph Fife,

Victor Randolph, San Francisco; Charles E. Winfermute, San Jose.

Deaths—Keith, Ivan Whitfield. Died at Beaumont, April 4, 1925, age 36. Graduate of Hahnemann Medical College of the Pacific, 1911. Licensed in California the same year. Doctor Keith was a member of the Riverside County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Miller, Byron Young. Died at San Francisco, March 30, 1925, age 48. Graduate of the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1914. Licensed in California the same year. Doctor Miller was a member of the San Luis Obispo County Medical Society, the California Medical Association, and the American Medical Association.

ALAMEDA COUNTY

The regular monthly meeting of the Alameda County Medical Association was called to order at the Ethel Moore Memorial building, Monday evening, March 16, by the president, H. B. Mehrmann. The program was arranged by H. Gordon MacLean and presented by the Providence Hospital staff. Two case reports were given—one by Hobart Rogers and A. H. Rowe, and one by C. A. DePuy.

The first paper, "Intestinal Drainage," was read by W. B. Palamountain. The discussion was opened by J. L. Lohse. In his paper, Palamountain stated that the predominant causes of death in intestinal obstruction are toxemia and exhaustion, and toxemia is the chief. Peristalsis is essential, and without it no bowel drainage can occur. Treatment must be directed to relief of the toxemia and removal of the obstruction. In advanced cases relief from obstruction is not sufficient; drainage of the bowel is essential. Releasing the obstruction is but a method of draining and very often insufficient. Washing out a paralyzed, toxic bowel, is the quickest and most certain method of treatment of toxemia, and is highly efficient. A properly placed vent tube is a most valuable preventive of distention.

The discussion of the paper on "Headache," by H. Gordon MacLean, was opened by W. H. Strietmann. Headache occurred as the chief complaint in 12.3 per cent of 2500 individuals examined. Migraine occurred in 44.3 per cent of the 307 individuals with headache examined. He further said that there are two underlying factors in migraine: (1) An inherited nervous instability; (2) an hepatic insufficiency with inability of the body to handle carbohydrates and fats, with resulting carbohydrate intolerance and the absorption of toxic fatty acids. He finds that treatment consists of: (1) Making the nervous instability less by rest, change of position, change of environment, and general health measures; (2) making the diet low in carbohydrates and free from fat, and giving bile salts to aid fat digestion.

P. L. Ansell gave a paper on "The Value of the X-ray in Diseases of the Digestive System, With Special References to the Negative Report." The discussion of this paper was opened by S. A. Jelte. The writer of the paper emphasized the careful study of those patients in which the indirect signs are the only roentgen evidence, and the use of anti-spasmodics, with a view of more definitely placing such cases either in the positive or negative column. He also stated that where the gall-bladder is suspected, a negative roentgen report on the digestive tract is most important and that localized tenderness in the lower right quadrant is exceedingly valuable in favor of chronic appendicitis, even when not restricted to McBurney's point.

The fourth paper, "Indications for Arthrodesis of the Sacro-Iliac Joints," was presented by O. P. Stowe. N. A. Cary opened the discussion on this paper. The writer mentioned the three types of chronic low back pain due to disturbance of the sacro-iliac joint, which present indications for operation. Type No. 1—Persistent pain following a shearing force applied to the lower lumbar vertebrae and sacro-iliac joints, through trauma or severe muscular effort. Type No. 2—Persistent low back pain following disturbance of the pelvic girdle, as fractures of the pelvic bones. Type No. 3—Persistent low back pain following operations under full surgical anesthesia. He said all of these cases have been treated for an extensive period by braces, plaster of paris casts, manipulation (with or without anesthesia), diathermy, baking, mas-

sage, without relief of pain, and that after operation (using a modification of the Smith-Peterson Sprengel's procedure) all cases had disappearance of pain and their full earning capacity was restored.

Others participating in the discussion of these papers were Roderick O'Connor, A. A. Alexander, R. J. Nutting, J. F. Carlson, and W. H. Sargent.

After the transaction of the routine business the meeting adjourned to the refreshment hall.

The annual banquet of the Samuel Merritt Hospital staff was held at the Hotel Oakland, Monday evening, March 30. One hundred and fifty guests enjoyed the occasion. The decorations came up to the Merritt staff standard and consisted of pink blossoms, most artistically arranged. The music was of a high order, two violin numbers being rendered by J. H. Todd Jr., son of the beloved senior member of the staff, James Hamilton Todd. The speaker of the evening was Allen H. Babcock, the son of Dr. H. P. Babcock, who was secretary of the association in 1871, serving later as treasurer, and in 1877 as president. This fact, when announced in his introduction by the president of the staff, C. L. McVey, recalled memories to some of days far away and long ago. Mr. Babcock spoke on "Mexico." Dr. J. Wilson Shields came from across the bay to help round out the evening, and Mr. Ezra Decoto, too, added his bit to the evening's enjoyment. It was an occasion long to be remembered.

Doctor Changes His Name—Doctor Boles Albert Rosenthal has had his name changed in the Superior Court of Oakland to Albert Boles. Hereafter, in all official and other documents, Doctor Boles will be recognized under his new name.

CONTRA COSTA COUNTY

Contra Costa Medical Society (reported by L. St. John Hely, secretary)—The regular monthly meeting of the Contra Costa County Medical Society was held at the beautiful home of Dr. John Beard at Martinez Saturday evening at 8 p. m., March 28.

Ralph H. Kuhns of San Francisco talked on the breast-feeding of infants. A lively discussion was carried on by the members. Resolutions of sympathy were passed by the members, and a committee of two was appointed by the Chair to draft resolutions and forward to the family of Dr. F. S. Cook of Brentwood, who died in Los Angeles, February 28, 1925. E. Merrithew and G. W. Sweetser were appointed as the committee. The next meeting will be held with one of the members at Pittsburgh, April 25. The subject will be selected later by the member with whom the meeting will be held. The Martinez physicians report a group of new arrivals from Butte, Montana, afflicted with simple goiter.

The following members and visitors were present: J. Edward Clark, John Beard, H. L. Carpenter, Frances Franklin, E. B. Fitzpatrick, L. St. John Hely, Denninger Keser, E. Merrithew, Rosa A. Powell, G. W. Sweetser, William A. Rowell, Elizabeth Redmond, R. N.; Lena Gardella, R. N.; Mrs. F. L. Risen.

FRESNO COUNTY

Fresno County Medical Society (reported by T. Floyd Bell, secretary)—Dr. Clifford D. Sweet of Oakland, formerly of Fresno, was the speaker at the luncheon of the Fresno County Medical Society, March 21, at the Hotel Fresno. There were thirty-two members and two visitors present, besides Dr. Sweet. Members—Aller, Anderson, Bell, Goldberg, James, Jorgensen, Lamkin, G. L. Long, Manson, Mathewson, Montgomery, Mitchell, Morgan, Madden, Pettis, Pomeroy, Schottstaedt, Sciaroni, Sheldon, Thompson, Tillman, Tobin, Tupper, Vanderbilt, and Willson.

Dr. Sweet spoke on "Diphtheria." Many said his talk was the best they had ever heard on the subject. He spoke of the high death rate from diphtheria, in spite of modern means of prophylaxis and treatment. Of course, part of this is due to the presence of carriers who do not suffer from the disease themselves, but spread it to susceptible persons. In regard to the diagnosis, he emphasized the importance of edema of the throat preceding the necrosis. He also stressed the point of giving antitoxin early in those cases in which the diagnosis is in doubt. The early diagnosis and the giving of antitoxin early is most important, before the toxin is fixed in the

tissues. He gave some experimental data in support of this, in addition to clinical data. Routine nose and throat cultures should be taken from every case of sore throat. However, the clinical findings should determine whether or not antitoxin should be given, and not the laboratory report.

In toxin-antitoxin we have a means of conferring active immunity. Every child under 6 years of age should be immunized with this mixture. Children over 6 should have the Schick test first. Six months after being immunized, all children should have the Schick test, to be sure of the immunity. This is now a harmless procedure and one of proven efficiency. The doctor should spread propaganda among his patients and the community about the value of this important procedure. He should be a teacher as well as a physician and not let epidemiologists take the lead in this. Sheldon, Cowan, and Ellsworth discussed the paper.

The regular meeting of the board of governors of the Fresno County Medical Society was held in President Anderson's office April 6. Those present were Cross, Couey, Miller, Tillman, Anderson, and Bell.

Mr. Speed B. Leas of the Aetna Insurance Company spoke to the board in regard to the group indemnity insurance. He explained that, under the new type of policy now issued, the insured is not protected in the use of x-ray and radium for therapeutic purposes. Even if he simply prescribed it or is a consultant, he is not protected. However, he may obtain this protection by the payment of an additional fee of \$162.75 per year, making the total yearly premium \$187.70. The secretary was instructed to notify the members of the status of policies held under the Aetna Insurance Company.

In regard to the closing of physicians' offices Saturday afternoons during the summer, Miller moved, Tillman seconded, recommending the closing of offices Saturday afternoons. Carried.

President Anderson reported that the San Joaquin Light and Power Corporation had discontinued medical care to their employes and the families of employes, except industrial accident cases of the employes. The employes now have a sick fund from which medical care will be taken, the patients having the doctor of their choice. The report was accepted.

The committee, in regard to the nurses of the Sun-Maid Welfare League practicing medicine without licenses, reported that they had taken the matter up with the governing board of this organization.

The secretary was instructed to get in touch with Dr. T. M. Hayden, an honorary member, and ask him to compile a history of our society.

Dr. Tillman moved, Dr. Couey seconded, that the new Constitution and By-Laws, as presented by the special committee, be recommended to the society for adoption. Carried.

Miller moved, Bell seconded, that the president appoint a committee to ascertain the methods of admission to hospital and clinic, and fees at the General Hospital of Fresno County and report. Carried.

The regular meeting of the Fresno County Medical Society was held April 7 at dinner at the Hotel Fresno. There were forty-six members and ten visitors present. Members—Drs. Aller, Anderson, Bell, Binkley, Burks, Couey, Cross, Crawshaw, Dixon, Diederich, Dahlgren, Dau, Foster, Goldberg, Garrett, Hare, James, Jorgensen, Kjaerbye, G. L. Long, S. M. Long, Mathewson, Miller, Mitchell, Morgan, Milholland, Madden, Peterson, Pettis, Pomeroy, Ransom, Rosson, Schottstaedt, Sheldon, Thompson, Tillman, Tobin, Traber, Trowbridge, Vanderburgh, Wahrhaftig, G. W. Walker, Weddle, Wheeler, Wiese, and Willson. Visitors—Drs. Terry, Seligman, Walters, De Lappe, Betts, Zumwalt, Newbecker, Yocum, and two others.

Dr. Cross, as chairman of the committee on revision of Constitution and By-Laws, presented a revised compilation of them. Dr. Couey moved, Dr. Trowbridge seconded, that the reading of them be postponed till next meeting. Carried.

The application of C. G. Newbecker of Lemoore for transfer of his membership from the San Bernardino County Medical Society was received, and on motion duly carried. The secretary was instructed to cast a ballot for his election to membership in our society.

The application for membership of J. M. Frawley of

Fresno was received and ordered placed in the proper channels for action.

Fred R. De Lappe of Modesto, the councilor from this district, was the guest of the society and spoke a few minutes on the activities of the state association.

Wallace I. Terry, Professor of Surgery at the University of California Medical School, was the speaker of the evening. He took for his subject, "Surgery of the Thyroid Gland." The classification of goiters he divided as follows: Adolescent or simple hypertrophy, colloid, hyperplastic or exophthalmic, thyroiditis, adenomatous toxic and non-toxic. Chronic thyroiditis goes hand in hand with exophthalmic goiter. The non-toxic adenomas become toxic in 95 to 98 per cent of cases if enough time is allowed to lapse. Malignancy has been present in Dr. Terry's cases in about 3 per cent, and is usually associated with adenomas.

The distribution of endemic goiter is practically confined to the area of the earth's surface which was covered by ice during the glacial period. The iodides were probably washed out of the soil in these areas. The types of goiter found in these regions are usually the adenoma and colloid. The exophthalmic type may be found anywhere. Goiter is several times more common in females than males.

Dr. Terry took up the diagnosis of the different types of goiter and pointed out the main characteristics of each. In most cases the diagnosis is not very difficult.

Iodine is a very useful agent as a preventive in certain goiters, but its use therapeutically is very limited. It helps and, at times, cures the adolescent type. It also helps some colloids. Adenomas are usually made worse by iodine. The iodine in the ash of burned sponges was used many centuries ago in the treatment of goiter. Plummer of Rochester first used Lugol's solution pre-operatively in exophthalmic goiter, and by this procedure has probably contributed more to the surgery of the thyroid than any other man in the last century. Lugol's solution is given seven to ten days before operation, and also for a short time post-operatively in small doses.

In the treatment he outlined the pre-operative care of the mouth, as well as other means to minimize infection. He uses nitrous oxide—oxygen as the anesthetic of choice in all his goiter work. He also spoke of some of the technical details of the operation itself. His patients leave the hospital four days after entry and three days after operation.

There were numerous questions asked by those present.

✽

HUMBOLDT COUNTY

Humboldt County Medical Society (reported by Lawrence A. Wing, secretary)—The general meeting of the Humboldt County Medical Society was held on January 28. A 6 o'clock dinner at the Eureka Gymnasium preceded our business meeting. The following officers were elected: President, John A. Lane; vice-president, Charles Caskey; treasurer, Mabel Geddes; secretary, Lawrence A. Wing.

On February 19 a regular meeting was held at the Union Labor Hospital. An excellent paper by B. M. Marshall on "Diseases of the Stomach" was enjoyed by a large percentage of our membership. The discussion following was opened by C. O. Falk and John N. Chain. An excellent lunch was served by the nurses of the hospital.

The March meeting was held on the 20th at the Tubercular School. A very interesting exposition of the Tubercular School was given by John N. Chain, M. D. We were taken throughout the school and the new contagious department, and shown how fresh air and heat are conveyed to the different wards. An interesting talk on the care and treatment of each patient followed. A very excellent lunch was served by the nurses of the school.

Our next meeting will be held at the Sequoia Hospital, April 28. Paper by O. R. Myers on "Discussion of Fractures."

✽

MERCED COUNTY

Merced County Medical Society (reported by Brett Davis, secretary)—The following members were present at the regular meeting of the Merced County Medical

Society on April 2: Parker, Davis, Lilley, Zirker, Mudd, Yacom, McDaniel, Kylberg, and Catton.

Curtis E. Smith of San Francisco presented the program for the evening, a talk on "Safe Handling of Mouth, Breast, and Uterine Cancer," thus making cancer week for us one of instruction for the medical men. A very general interesting and instructive discussion followed the talk.

In March, J. C. Robertson of Modesto gave a talk on his experiences on his recent trip to London and Paris hospitals. Dr. Robertson stated that the European methods of preparation and sterilization for operations are not so carefully done as in the United States.

Dr. Fred R. DeLappe of Modesto also told us what the State Medical Society and Council have been doing for us.

✽

RIVERSIDE COUNTY

Riverside County Medical Society (reported by Thomas C. Card, secretary)—The regular meeting of the Riverside County Medical Society was held on April 13 in the Riverside Community Hospital. The program presented was by Ernst F. Mueller, M. D., Hamburg University, Germany, on the "Importance of Skin Functions in Medicine," and W. W. Roblee, M. D., Riverside, on "What Do We Know About Blood Pressure?"

Dr. Mueller holds the chair of Privatdozent Internal Medicine, Hamburg University, and has been for the past year and a half on leave of absence from the university for research work in this country. For the past year he has been carrying on his research work with Dr. Fordyce of Columbia University and with Dr. Peterson of Chicago. Mueller illustrated his talk with graphic charts and told of experimental work done on humans, demonstrating the fact that the skin holds a hitherto unknown important function in its control over the function of other organs.

In the second paper, Roblee brought out the known facts in the etiology and treatment of hypertension. This review was of very practical worth.

One of our members, Dr. Ivan W. Keith of Beaumont, died on April 4, after a few days' illness of influenza pneumonia.

The members of the County Medical Society are co-operating with the Riverside County Clinic in the examination of the pre-school age children. This examination will be conducted May 4 to 12.

✽

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reported by Bert Thomas, secretary)—The regular March meeting of the Sacramento Society for Medical Improvement took on its usual festive color, March 17 being the date set for the annual banquet. Skipper Charles B. Jones and his able committee decided on a real innovation this year. The surging waters of the Sacramento River having subsided, they decided upon a nautical banquet. The steamship Enema had all of her holiday flags drawn from her locker before Admiral Scatena took his post. The weather god was kind and produced such a beautiful evening as is only found on the Sacramento River for the boat ride.

The senior medical officer of the night was recruited from San Francisco, in the person of Dr. Alanson Weeks. He proved successful enough to return a blank form, No. 996 (United States Naval Regulation), which means that the mess served, from the pate de fois gras (a la Loizeaux) down to the demi tasse (a la "Wally" Briggs), caused no casualties.

The only regret of the committee was that one of the very smallest gatherings that ever attended any medical banquet boarded the jolly ship. Only approximately one-quarter of the membership of the society attended.

The Admiral docked his ship in the wee small hours.

✽

SAN DIEGO COUNTY

San Diego County Notes (reported by Robert Pollock)—About twenty members of the County Medical Society motored over to Riverside on the occasion of the Southern California Medical Association meeting, and enjoyed one of those excellent programs so characteristic of this society. It would be difficult to conceive of a more suitable meeting place for a small scientific gathering

than the Mission Inn at Riverside, with the genial hospitality which Host Miller so capably expresses.

At the recent election the voters of San Diego granted to the United States Government an extra strip of land in Balboa Park, upon which to make an extension to the Naval Hospital. This building is now rapidly approaching the maximum capacity, as originally planned—something around a thousand beds. The Government has left nothing undone to make this one of the best-equipped hospitals in the service.

It is with regret on the part of the local profession that we learn of the resignation and withdrawal of Captain Wieber as medical head of the Naval Hospital. Dr. Wieber has always been extremely courteous to members of the profession outside of the Navy as well as in, and has made hundreds of friends in and about San Diego who will miss his genial countenance and pleasing personality.

The April meeting of the county society will greet Charles F. Kofoed, Ph. D., of the University of California, who will discuss the question of intestinal parasitism, a subject on which he is splendidly qualified to speak as an outstanding authority.

A Visit to a Floating Hospital (by E. B. Nelson, M. D.)—Through the kind invitation of Commander Owen and his medical staff, members of the San Diego County Medical Society had an opportunity to inspect the United States Hospital Ship "Relief," the regular March meeting being held on board Saturday, March 14.

A large motor-boat and several speedy launches were filled with adventurous M. D.'s, who enjoyed a ride of about two miles from the foot of Broadway to the hospital ship, through a wide, watery avenue bounded on each side by brilliantly lighted battleships, cruisers, destroyers, and with busy little speed boats passing in every direction. Listening to that constant put-put-put gives a slight appreciation of the importance of gasoline to the Navy.

On boarding the Relief, it was apparent that a new hospital, completely equipped and operating at full blast, had been acquired by San Diego overnight. This hospital is of all-steel construction, and architecturally the equal of any of its size. It has, however, one defect which every landsman would notice—they forgot to put in a front door, and you enter by the fire-escape.

The surgery, the x-ray department, laboratories, cystoscopic room, eye, ear, nose, and throat departments are all supplied with modern equipment and operated in the most up-to-date manner. The Government has not spared expense in caring for the sick and injured of the Navy. A bed in this hospital is said to cost approximately \$25 a day for each patient. In return for this, the patients get more frequent changes of climate than in other institutions.

In constant competition with the exhausts of passing motor-boats, two interesting papers were read and discussed. Dr. Thompson gave his experience with ethylene as an anesthetic, presented in a practical and convincing manner. The very best character of clinical papers can be prepared by drawing on the experience of our own society members. Dr. Sherrill's paper on the "Acidosis of Nephritis" explained clearly some of the more recent conceptions that frequently confronts every general practitioner.

Refreshments and a social time followed.

Fully a hundred members of the County Medical Society then made a successful exit by the fire-escape, and a happy trip back through the brilliantly lighted waters of the bay. Not one case of seasickness was reported.

✽

SAN FRANCISCO COUNTY

Doctor Shiels Honored—Colonel (Doctor) George Franklin Shiels of San Francisco has been notified of an award of two citations for bravery in the Spanish-American War. Shiels now holds the Congressional Medal of Honor and the Croix de Guerre with palms, and has been cited for the Distinguished Service Cross.

Meeting of the Section on Urology, San Francisco County Medical Society, March 31, 1925 (reported by Miley B. Wesson, M. D., chairman)—The program was devoted to some of the common diagnostic and therapeutic errors in urology and the overlapping specialties. P. K. Gilman read a paper on "General Surgical Condi-

tions Simulating Lesions of the Right Kidney." He reported a series of six cases, all having been wrongly diagnosed as surgical kidney lesions: (1) A subdiaphragmatic abscess containing 500 cc. pus, probably secondary to an attack of appendicitis two months before; (2) an abscess in the upper pole of the kidney, due to an extension of a liver abscess, pyelogram simulating that of a stone in the kidney; (3) a narrowing of the ureters, following the dilatation of same, a mass over the right kidney and symptoms of appendicitis disappeared; (4) following a severe attack of tonsillitis, symptoms in the upper right quadrant developed; after the drainage of a right empyema they disappeared; (5) an enlarged kidney surrounded by an inflammatory mass proved to be an amebic granuloma of the intestine; (6) a fistula in the right flank persisting from a former operation proved to be, not from a tuberculous kidney, but from an osteomyelitis of the twelfth rib.

Urinary, biliary, and renal colic, as well as gastrointestinal angio-neurotic edema must be carefully differentiated, if unnecessary kidney surgery is to be avoided.

The discussion was opened by Herbert Gunn, who stated that, from the standpoint of tropical medicine, three infections are of interest to the urologist. (1) Liver abscesses cause the most confusion; many a suspected perinephritic abscess proves to be an amebic abscess, even though the stool examinations are negative; on the other hand, the presence of ameba in the bowel must not lead one to make a diagnosis of liver abscess without very careful differentiation; in amebic abscess cases, there is generally a history of fever over a long period. He had one patient who developed an amebic abscess fifty years after an attack of dysentery; the stools showing no ameba during the interim. (2) In bilharziosis, blood and pus occur in the urine. (3) *Filaria* with a low-grade chyluria in the presence of blood has caused many a tentative diagnosis of tuberculosis of the kidney.

R. R. Newell stated that, in the absence of a pyelogram, filling the colon with air helped differentiate the kidney behind from the liver in front.

William E. Stevens reported a case seen in Germany last year, where a diagnosis of a surgical kidney was made on the presence of a mass in the upper right quadrant and blood in the urine; after the operation, the diagnosis was changed to that of retroperitoneal sarcoma.

Stanley Stillman reported a ruptured pyonephrosis from a pin in a retrocecal appendix; he has seen frequently an acute appendicitis diagnosed when there were merely showers of uric acid crystals coming down the ureter; a four months' extra-uterine pregnancy, because of the close relationship with the ureter, caused blood in the urine and a diagnosis of kidney tumor; any suppurative condition overlying any part of the ureter causes pus and blood in the urine; he does not believe in indiscriminate cystoscopies because of the danger of anuria from the passing of the catheter; death has followed such an anuria and where pyelograms have been made, the pyelogram medium was blamed for the death, whereas it was from the passing of the catheter. He had one acute retrocecal appendix where complete anuria followed catheterization of the ureters, and though the patient did not die, he was very sick. He recently saw a case of mechanical obstruction of the bowel from a ureteral calculus; he did not operate, for, although all the symptoms but one warranted a diagnosis of acute intestinal obstruction, there was no peristalsis, and that one symptom indicated no intestinal obstruction. A diagnostic point is the question of radiation of pain; pain in the kidney radiates, whereas that of the retrocecal appendix is merely referred.

James R. Dillon said that many genito-urinary cases seen by the general surgeon or internist have no urinary symptoms, and hence go undiagnosed; the only cases referred are those that have definite symptoms; all cases with blood or pus in the urine, tumor in the upper quadrant, confusing x-ray shadows, or indefinite abdominal pain should be seen by an urologist.

A. B. Spalding read a paper entitled, "Skene's Glands, Bartholin's Glands, and the Cervix as Foci of Infection." A series of thirteen cases was reported in which arthritis was cured or improved by operating upon one of these three foci; glands with free drainage are not of interest from the standpoint of arthritis; the gland that has no drainage encourages the organisms to pass through the

lymphatics to the lymph glands, and from them absorption takes place to the body. The cervix has the best drainage and is the least dangerous, whereas Bartholin's glands have the poorest drainage and are the most dangerous; if the gland suppurates and breaks down, or if it forms an aseptic cyst, it is harmless, but if it forms a septic cyst it is dangerous. Temporizing methods are worthless; the only surgery indicated is radical excision of the entire infected area.

William E. Stevens, in opening the discussion, reported that the examination of 3429 prostitutes showed these glands to be infected in 45.5 per cent of the cases. He advised destruction by fulguration or by cautery.

R. S. Zumwalt called attention to the fact that very commonly the foci first removed are not the ones responsible for the arthritis.

H. A. R. Kreutzmann very seldom finds the gonococcus in Skene's glands in the acute stages; the glands are hard to find because of the atypical position of the ducts; he injects 0.5 cc. of 4 per cent mercurochrome in the region of the ducts, and the resultant induration generally destroys the glands.

T. H. Kelly stated that any break in the mucous membranes of the body serves as a focus; the only dangerous foci are the chronic ones. The internist is always in doubt as to which focus to first consider in looking for the cause of arthritis; it is very easy to remove a large part of the original equipment of the body, and in the end find that only harmless foci have been disturbed and the dangerous ones overlooked. A careful history is of the utmost importance in deciding which is the important focus. If there is drainage there will be no absorption, and yet dentists still dam up discharges by placing gold caps over diseased teeth.

L. W. Ely stated that chronic arthritis is rarely connected with the female genitalia, whereas acute arthritis is not uncommon. Everybody treats a joint; pain is called arthritis or neuritis, and the teeth and tonsils come out, although teeth are never responsible for arthritis; the foci of arthritis are closed ones and are commonly found in the deep urethra—in the prostate and seminal vesicles. A dead tooth lies in a suppurative cavity and keeps open a portal of entry of infection to the body, but is itself never a focus of infection. Aspiration of a joint furnishes only confusing information as to etiology; the organisms may be in the fluid one day and the next day be in the tissues, hence the differences of opinion advanced by various surgeons.

"Report of Cases of Tumor of the Bladder; Radical Resection Compared to Conservative Forms of Treatment," by L. R. Reynolds. Tumors of the bladder treated in Stanford Hospital in recent years were analyzed and tabulated. The prognosis is generally considered hopeless, hence the only question is the best method of handling them. Three methods are considered: (1) Resection of the tumor, (2) a wide resection of the tumor with possible transplantation of the ureters, (3) and use of fulguration and radium needles. Results with radium are unsatisfactory because of the tendency to form rectovesical fistulae. The patients treated by radical wide resection have been made the most comfortable and have the best chance to live.

R. L. Rigdon, in opening the discussion, stated that he believes in being as radical as you can and never temporize; if he uses radium needles, he does it only under direct vision through a suprapubic opening. He has never felt justified in doing a radical resection and using radium at the same time.

Lloyd Bryan, discussing the paper from the standpoint of the use of deep therapy, stated that the deep therapy statistics will always be bad, as the roentgenologist sees only the inoperable cases; it has now been proven that the use of radium alone is worthless, but that combined with x-ray it is very efficacious. He reported some startling statistics from South America; one authority had six hopeless cases well two years after deep therapy; and another with the use of diathermy and x-ray had only two failures in eleven hopeless cases. An analysis of statistics from John Hopkins Hospital shows that 25 per cent of bladder tumors are inoperable, and these are treated by means of radium implantation through suprapubic openings and x-ray. Papillary carcinoma disappear

with radium, but recur; if x-ray is then used they stay cured.

J. R. Dillon believes that granular tumors should be operated upon, and smooth, glistening tumors fulgurated; that tumors which are not destroyed with one fulguration should be immediately operated upon before the scars from fulguration and from radium make it more difficult.

L. C. Jacobs is very partial to the cystogram, in arriving at diagnosis; he uses radium seed through a cystoscope at intervals of three weeks. Inasmuch as most of these cases die shortly, whether they have been treated by radical or conservative surgery, the patients are made much more comfortable during their last days and can continue with their work if palliative measures are used; otherwise, they are converted into bed-ridden patients, and for that reason he hesitates to advocate radical surgery.

L. R. Reynolds was elected chairman, and Dr. M. Silverberg secretary for the coming year.

St. Joseph's Hospital—St. Joseph's Hospital staff, San Francisco, met April 8, A. S. Musante presiding. William Quinn opened on "Observations With Mercurochrome," including cases of generalized infections of various character which showed improvement. He also presented a history of a newborn with rudimentary cecum and colon. Alex Keenan, W. C. Cummins, and Ethan Smith discussed the subject, bringing out the importance of the method of administration of the drug, the apparent help of the latter in a case of subcutaneous induration, probably elephantiasis, and the advantage of the same in treating infections that may be luetic, respectively.

Frank Lowe showed moving pictures of "Treatment of Rachitic Limbs," demonstrating the gaits before and after mechanical braces and the application of the latter, which obviates operation.

J. M. Stowell described "Remedial Partial Gastrectomy," and quoted a case of ulcer of the lesser curvature, upon whom a gastroenterostomy had been done at the same time. G. D. Schoonmaker discussed the paper.

George Wolf spoke on "Ferretting Obscure Malaria." A slightly acid Wright stain was recommended for staining the organisms in the blood. Suppositories of muriate of quinine had been found advantageous in the treatment. Howard Dixon and A. J. Remmel spoke on "Prostatectomy—After Treatment." R. H. Dunn reported on the opportunity for specialists in the clinic.

M. B. Ryer presented a history of "Curative Hysterectomy Fifteen Hours After Rupture," and J. C. Newton was called upon to discuss it.

Mr. Leon Kuttner, one of the generals in the drive for a new fireproof hospital building, enthused those present with his earnest plea for the success of the campaign.

St. Luke's Hospital—The regular monthly meeting of the St. Luke's Hospital Clinical Club was held on Thursday, April 9, at the hospital. Following lunch, Dr. E. I. Leavitt, Chief of Anesthesiology for the hospital, presented a paper on "Rectal Anesthesia." The technique of this procedure was gone into carefully and its advantages and disadvantages noted, the former, in the speaker's opinion, being preponderant. The comparative safety, comfort, lack of surgical shock, and avoidance of heat loss in this form of anesthesia, and its superexcellence in surgery of the head, neck, lung, and thorax, were all emphasized.

Considerable discussion followed, participated in by Drs. Ryfkogel, Kilgore, Gibson, and others. Ryfkogel mentioned the presence of sudden vomiting in several cases of abdominal surgery that he had witnessed. He stated that the amount of rectal anesthetic used in these cases was less than the speaker of the day had outlined. Kilgore thought that unpleasant complications, such as vomiting, etc., arose from the fact that the patient was not given deep anesthesia. He stressed the importance of great care after such operations; that the rectum should be washed out carefully and the patient watched for a long time. All speakers had noted the smoothness of convalescence in such cases.

In closing, Leavitt reiterated the importance of a slight induction anesthetic of nitrous oxide and ether, and a preliminary hypodermic of morphia and scopolamine. Where this is done, there is no ejection of the rectal anesthetic.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by the secretary, Alex C. Soper)—The regular monthly meeting was held at the Cottage Hospital, April 13, President Nuzum in the chair, and thirty-one members, three interns, and the superintendent of the Cottage Hospital, and four other guests present.

The first business was the admission of Horace Hagen and Kent R. Wilson, both of Santa Barbara, to membership. They were unanimously elected.

The principal address of the evening was a talk on "Allergy," by George Piness of Los Angeles, introduced by a discussion of its chemical phases by Gordon Alles, A. M., his associate. Piness dwelt especially upon the clinical side of the work, and cited many cases, and showed lantern slides.

Owing to an unusual press of routine business, a discussion of this interesting topic of Allergy was omitted. But a motion of a vote of thanks was unanimously passed and given standing.

Dr. Eaton, the City Health Physician, spoke on the necessity of city ordinances to give power of quarantine in cases of typhoid carriers and diphtheria carriers, and a motion was duly passed to authorize the president to appoint a committee therefor.

An invitation from the Lompoc Valley Chamber of Commerce to meet with them on Monday, May 4, was unanimously accepted, a vote to make it a special meeting being passed.

Telegrams to State Senator Hollister regarding the Optometry Bill No. 201 were read.

The matter of the High School Annual's soliciting advertisements from members of the society, in the form of insertion of name, specialty, and office address, was dropped as having been ruled upon in a similar case in 1924 as not ethical.

St. Francis Hospital, Santa Barbara, Accredited for the Training of Interns—The Sisters of the St. Francis Hospital have been notified by the Council on Medical Education and Hospitals of the American Medical Association that their hospital has been placed on the approved list, in the following letter:

"The Council very much appreciates the excellent spirit of service which prevails in your hospital, and especially is it gratifying to note the high stand which you have taken with regard to the character and qualifications of the doctors who are permitted to use the hospital. The necessary steps have been taken to place your hospital on the list of hospitals approved for internships, and a notice of this accrediting will be published in an early issue of the Journal of the A. M. A.

"In this connection, it is the desire of the Council, and I am sure it is the sincere wish of Doctor Musgrave and Doctor Magan, that we may all be of assistance to you and may encourage you in striving for better and better things all the time. Kindly call on any of us for any assistance that we may be able to render you."

Good Theories That Don't Work—Everyone may have occasion to consult a physician, but comparatively few can judge of the qualifications of learning and skill which he possesses. Reliance must be placed upon the assurance given by his license, issued by an authority competent to judge in that respect, that he possesses the requisite qualifications. Due consideration, therefore, for the protection of society may well induce the state to exclude from practice those who have not such a license, or who are found upon examination not to be fully qualified.—H. E. Kelly, member of Chicago Bar.

Quantitative Changes in Hepatic Glycogen in Anaphylactic Shock—F. I. O'Neill, W. H. Manwaring, and H. Bing Moy, Stanford University, Calif. (Journal A. M. A.), found that glycogen disappears almost quantitatively from the canine liver during the first fifteen minutes of anaphylactic shock. No conclusion is as yet drawn as to the mechanism of this hepatic glycogen disappearance, nor as to its clinical significance. These observations are in line, however, with the initial hyperglycemia in guinea-pig anaphylaxis, recently reported by Zunz and La Barre.

Utah State Medical Association

SOL G. KAHN, Salt Lake City.....President
 WILLIAM L. RICH, M. D., Salt Lake.....Secretary
 J. U. GIESY, Kearns Building, Salt Lake City,
 Associate Editor for Utah

ARE WE SCIENTIFIC?

It is spring! The trees are budding—crocuses and dandelions star the grass. Fifty years ago our grandmothers were feeding our fathers and mothers-to-be sulphur and molasses, with maybe a little cream of tartar, and making them guzzle sassafras. Two thousand years ago and more the ancients were celebrating the Spring Festivals. The Egyptians were welcoming the northern swing of Ra—the Giver of Life, before that.

Today we have horseless carriages, airplanes, wireless telegraphy, the radio, and what have you? Also we have foodless food and infected teeth. We have "metabolism," insulin, hexylresorcinol, mercurochrome, arsphenamine, crowded tenement districts, caloric feeding, an increasing incidence of cancer, birth control and contra-ceptionists, a high cost of living and an almost equally high cost of death.

Ra—God or Nature—(this isn't a religious discussion) we regard as the source of Life. The ancients worshiped the sun, because they recognized the fact that Light *was* Life. Our grandmothers cleaned house and the physical systems of their children, because they recognized the need. Any consistent observer knows there is a solstice in the vital forces of the body, as well as in the seasons. Fishermen know that as the spring advances and the schools of fish swing north, there is a rise in medicinal efficacy in the oil extracted from the cod.

The law of cause and effect in all things is as immutable as the trademark of a well-known life insurance company. Get away from that fact and you're going to bog down as effectually as a four-year-old vintage tin Lizzie in a ditch.

God, Ra, or Nature, meant mankind to eat. That's why he was given teeth. And before that he was meant to be nourished from his mother's teats. Teeth, like muscles or brain tissue, need exercise to preserve their health. The food has been provided, but "scientifically" how is it being used? A soft job or a soft pabulum will not exercise teeth or brain or muscles. Laugh that off. But before you do so, think it over as applying to diseases of the mouth, with their multifarious systemic results. Furthermore, a devitalized food or a partially devitalized food will not furnish the full measure of nourishment. After all, what is the vitamin of which we speak today but the essential characteristic life element of a given food. How about deficiency diseases from this viewpoint? A lack of fresh vegetables means a lack of soil-born iodine—the spring solstice, unless guarded against, means a shortage in the blood potassium and calcium, after the winter lowered sunlight, which is essential to their binding in the tissues. Lack of potassium means weakened muscle action, lack of lime means digestive effects, as well as possibly diseased teeth. And any of these lacks may mean a lot of other things. Cod liver oil,

as proved today, is of value in rickets, because it is an actino active substance—a substance that has actually absorbed the actino active quality of sunlight and will give it off upon ingestion, as will also the yolk of egg.

These are but points. But if there is a law of cause and effect, then all these things will affect "metabolism"—pretty word. Metabolism, like vitamin, is a mouthful, which means nothing unless we get back to first principles more or less. And the first principle of life is that the best food is live food, not food doctored or treated or pasteurized and sterilized half to death. Go to the calf, physician. Ask any calf if milk isn't the best food. Ask any calf if it prefers it condensed or modified. Personally, we are of the opinion that the best food for infants also is milk. And we don't mean maybe, and we don't mean condensed. We mean the milk from its mother's breast, provided her "metabolism" is such that she can feed her infant; and after that milk from some contented cow, properly prepared and served. And we wonder if all of us who treat human ailments would think of these things, and preach them, whether we wouldn't find that it made a big difference in the general state of health.

Are we scientific? Sure we are. We've found out a lot of things old Doc. Jones with his little black bag and his horse and buggy knew nothing about. And it's right we should be. More honor to those who have and will advance the knowledge of our craft. But in the midst of it all let's not forget that Life is Life, and its laws unchanging, and that "metabolism" means just simply the working out of those laws on a basis of supply and demand, and that an unbalance in that one element, with its resultant effect on the cell functions of the body, is the primal difference between a state of health and disease. Green spectacles won't turn shavings into grass.

Utah News Notes (reported by J. U. Giesy, associate editor for Utah)—One of the outstanding items of interest to the medical men of the state is the opening of the new Diagnostic Laboratory at the State Capitol in connection with and directly under the control of the State Board of Health. This, it is hoped, will put the availability of laboratory diagnosis within the reach of all men who desire to exercise the privileges extended.

Under the present postal arrangements, specimens may be mailed on zone rates as fourth-class matter (parcel post) at regular rates plus the new service charge now in effect. This insures the transportation of the specimens in the regular mail-sacks and prompt delivery, especially if the package be insured to guarantee safety and attention. Outfits for shipment will be furnished to any physician who applies to the Board of Health, and these should be employed in order to insure, not only the correct transmission of the specimens, but to avoid all confusion in their handling, since each outfit is standardized. The board has put out a very comprehensive booklet covering all the salient points of the service it is intended to render, together with a card designed to carry the request for outfits desired. The laboratory itself is a very complete affair.

Doctor T. B. Beatty, secretary, is to be congratulated upon the accomplishment of this service, which is a thing for which he has consistently worked for a considerable time.

As a part of their health educational campaign, President J. Z. Brown of the Salt Lake County Society, has appointed a committee, consisting of W. R. Calderwood,

T. C. Gibson and Claude Shields, to arrange for and supervise the broadcasting of a series of lectures on subjects deemed timely and calculated to prove of interest to the general public. It is hoped that such a series of lectures will not only do much to counteract misinformation, but to bring the laity into closer touch and understanding with physicians, their objects, endeavors, and aims.

Death of E. D. Woodruff—Doctor Edward Day Woodruff died recently of angina pectoris at the age of 74.

Dr. Woodruff was born in Bonus, Boone County, Ill., on September 24, 1850. Early in life he entered the employ of the St. Louis Iron Mountain and Southern Railroad as an axman on a surveying gang. During the reconstruction days that followed the Civil War, he assisted in mapping the road's future lines through Missouri and Arkansas.

Forced by malaria fever and rheumatism, contracted while tramping the swamps of the Middle Western States, to give up the engineering profession, he returned to Chicago to attend a medical school. In 1879 he was graduated, and in 1880 he prefixed Dr. to his name and began practicing in Chicago.

In the summer of 1880, while on a visit to the West, he was summoned to Rock Springs to attend several persons injured in a mine disaster. After filling the immediate needs, he was offered and occupied the position as chief surgeon for the Union Pacific Railroad and Coal Company.

Dr. Woodruff is survived by four children: Mrs. Lesley D. W. Riter and Mrs. Helen M. Hill of Salt Lake, Mrs. Virginia M. Gifford of Burlingame, and E. R. Woodruff of Los Angeles, and two brothers, J. D. Woodruff of Shoshone, Wyo., and R. D. Woodruff of Salt Lake.

Salt Lake County Medical Society (reported by M. M. Critchlow, secretary)—The March meeting of the Salt Lake County Medical Society was held March 23.

President John Z. Brown, fifty-nine members, and three visitors were present.

L. N. Ossman demonstrated a case of dislocation of the right shoulder with an excellent result following treatment, which was outlined.

The scientific program was a symposium on peptic ulcer. "The Medical Diagnosis and Treatment" was discussed in detail by R. T. Jellison. "The X-ray Diagnosis and Differential Diagnosis" was taken up by J. P. Kerby, who illustrated his points with lantern slides. "The Surgical Treatment" was taken up by E. F. Root, who stressed the surgical judgment and individualization of the patient rather than the operative technic, and emphasized the importance of the prevention of cancer. These papers were discussed by H. T. Anderson, Fuller B. Bailey, A. A. Kerr, and George F. Roberts.

E. F. Root reported for Fred Stauffer on the proposed new medical building, stating that insufficient stock had been subscribed for as yet. President Brown announced the committee to supervise public lectures: W. R. Calderwood, chairman; T. C. Gibson and C. L. Shields.

The applications for membership of Drs. Hueter, Wright and Young were read and referred to the board of censors.

The April meeting was held April 13, as the guests of T. B. Beatty, secretary of the Utah State Board of Health. President John Z. Brown, eighty-four members, and five visitors were present.

A paper on "Acute Osteomyelitis" was presented by J. C. Landenberger. The essayist considered the etiology, bacteriology, pathology, clinical course, and differential diagnosis. The anatomy of the bones and x-ray of osteomyelitis were illustrated by lantern slides. Operative treatment was outlined. Discussants were D. K. Allen, T. A. Flood, S. H. Allen, A. L. Brown, S. C. Baldwin, A. J. Hosmer, W. F. Beer, L. N. Ossman, and S. D. Calonge.

"Aspects of Industrial Practice" was the title of an essay by A. Jack Hosmer. He compared the work of the industrial surgeon of today to that in the past, described the cases that industrial surgeons are called upon to treat, and outlined the importance of prevention of disease and injury in industrial practice. Discussants included E. Spencer Wright and F. D. Spencer.

Fred Stauffer, in reporting for the building committee,

said that ninety-five doctors had subscribed for stock, and announced a meeting of the subscribers at the Hotel Utah, April 14.

T. C. Gibson reported verbally for the Committee to Supervise Public Lectures. The secretary announced that he would take orders for the new caducei. A. L. Huether, Wallace H. Wright, and Clark Young were voted upon and unanimously elected to membership, forty-eight members voting.

T. B. Beatty spoke about the new State Health Laboratory, and announced the prescription pharmacy would receive specimens at any time, day or night, for the laboratory.

Refreshments were served by the personnel of the Utah State Board of Health, after which the new laboratory of the State Board of Health was inspected.

Nevada State Medical Association

W. M. EDWARDS, M. D., Mason.....President
CLAUDE E. PIERSALL, M. D., Reno.....
Secretary-Treasurer and Associate Editor for Nevada

Washoe County Medical Society (reported by Henry Albert, secretary)—The society met in regular session in the rooms of the Chamber of Commerce, April 13, 1925, Vice-President G. E. Piersall presiding.

Minutes—The minutes of the previous meeting of March 10, 1925, were read and approved.

Program—Mr. Gilbert of the Bell Telephone Company had a class in emergency work demonstrate two first-aid procedures: (1) a procedure in connection with an automobile accident, and (2) one of resuscitation of a man overcome in a gas-filled room.

Mr. Bernard, representative for the new Physicians and Surgeons' building, which Mr. Harry Sheeline is planning on constructing on Virginia street, described the construction of the contemplated building, and stated that they planned the construction of a room which would be suitable for use for the Washoe County Medical Society.

Dr. T. W. Bath demonstrated the Soresi direct blood transfusion apparatus, and offered its use to members of the society.

C. E. Piersall referred to a new medical automobile emblem which is copyrighted and protected by the American Medical Association and will be sold to members of the association only.

Attendance—Members: Albert, Bath, Brown, Caples, DaCosta, Pickard, Piersall, Servoss, Walker. Also Mr. Gilbert and his class, Mr. Bernard and a class of girls who were interested in the first-aid demonstrations.

CORRESPONDENCE

Doctor C. A. Nahl of Sacramento, in calling our attention to the following notes the warning that physicians who may be inclined to become careless will do well to heed:

DR. CRESS WANTS INSANE WARD AT COUNTY HOSPITAL

City Health Officer Declares Present Method Treating Patients Is Old-Fashioned

The need of a psychopathic ward at the Sacramento County Hospital, where insane suspects can be observed under proper conditions instead of being placed in the county jail, as is the present custom.

Dr. Cress declares that the method of handling insanity cases in Sacramento County is far behind those used to treat mental cases in other counties of the state. Conditions in Sacramento, he said, have not improved during the past fifty years.

The health officer discussed the subject in a letter to and at the request of Judge Pullen. It follows in part:

"Under the present conditions an insane man is turned over to the sheriff and the patient is placed in jail until a board is appointed to examine him as to his alleged insanity. This board consists of a superior judge and two physicians.

"After the examination by this board, if the patient is considered insane, he is ordered transferred to a hospital for the insane by the judge. Under this system mistakes are bound to occur, as the time allotted for examination and observation is entirely too brief. If the patient is violent it is practically impossible to take care of him at the jail, and there is no hospital in the city properly equipped to care for him.

Typhoid Not Insanity—"Recently a man, apparently insane, was found wandering about the streets by the police. He was placed in the city jail and after he was there twenty-four hours, it was decided he was insane. He was ordered before a board, and while being transferred to the county jail he collapsed. He was transferred to the county hospital and died within forty-eight hours. Post-mortem examination revealed the man died of typhoid fever.

"According to our modern conception of insanity, an insane man is not a criminal, but a sick individual and should be treated as such and not placed in jail. I would recommend that all insane cases or cases suspected of being insane be confined to a psychopathic institution, where they can be properly observed and their exact mental status determined before final disposition is made of the case.

"I am of the opinion that the county hospital is the proper place for such cases, but I am informed that under the present plans there are no facilities at the institution for the care of these cases. I would recommend that facilities be provided at the county hospital, where at least ten mental cases can be properly taken care of."

In this connection, and of particular concern to California physicians, is the following question of a California physician and the answer supplied by the A. M. A. and published in that journal:

Liability for Certifying to Insanity

To the Editor—A physician, licensed to make insanity examinations, is requested to certify to the insanity of some named person. In support of the request there is submitted an affidavit made by a stranger to the physician, in which he has sworn to the supposed facts of the case and that the person whose insanity is to be certified to is in fact insane. The physician has no personal knowledge of the case. He makes no examination of the supposedly insane person, for we have no facilities here for keeping such patients under observation. If under such circumstances, and relying solely on the affidavit of a stranger, the physician certifies that the person named therein is insane, is he liable in damages if ultimately it be proved that such was not the case?

_____, California.

ANSWER—A physician who certifies to insanity, whether

a licensed examiner in insanity or not, must use due care and ordinary knowledge and skill, and must exercise his best judgment. Furthermore, he must comply strictly with the requirements of law with respect to the procedure leading up to the issue of his certificate and to the form and execution of the certificate itself. A physician who certifies to the insanity of any person on the sole basis of an affidavit made by a third person, whether by a stranger to the physician or not, without personal knowledge on the part of the physician as to the truth of the facts sworn to and without examining the supposedly insane person, can hardly be said to have met the requirements stated above. Even though a community has no place in which persons suspected of being insane can be held under observation, a physician may still examine the suspect under such conditions as are possible. The fact that he cannot make such an examination as he would like to make does not excuse him from making such an examination as he can make, and he should make that examination or else not certify to the mental condition of the patient. Conceivably, a licensed examiner in lunacy might be authorized by statute to certify to insanity on the basis of an affidavit and without an examination of the patient, but an examination of the laws of California has disclosed no statutory authority for such a procedure. It is believed that a physician who certifies to insanity on the basis of an affidavit made by a stranger and without having personally examined the patient would be liable in damages if the certificate proved false.

Medicine Before the Bench

Findings and Comments of the Courts on Acts and Omissions of Doctors

(EDITOR'S NOTE—*The law reports contain many interesting decisions, involving the reputations and fortunes of doctors. In this column in each issue a brief summary of one or more decisions and comments of the several courts of last resort upon the cases will appear. The matter will be selected by our general counsel, Hartley F. Peart, who, with Hubert T. Morrow, attorney for Southern California, will contribute from time to time.*)

In a comparatively recent decision involving the liability of a hospital and its staff physicians for the alleged wrongful death of a patient, it appeared that the deceased had been injured in falling from a ladder, resulting in a fracture of the skull. No operation was performed, and the plaintiff, the surviving wife of the deceased, brought suit claiming that the defendants negligently failed to perform an operation which would have saved her husband's life. A post mortem disclosed a blood clot on the brain about the size of a fist, and at the trial a physician testified that this could have been removed by a simple operation and would have saved the patient's life.

The court in discussing the statute in the state involved, providing for an action for wrongful death through negligence, held that where there is a cause of death already in motion, mere non-action or non-feasance is not the act contemplated by the statute. In other words, a failure to save life is not regarded as a positive act which causes death. In this connection, the court said:

"We fail to see how any 'failure to arrest the effect of said injury' by surgical operation can be said to be the cause of death as these words are used in the statute. To say that the failure of a physician to prevent death is the cause of death, is merely to play with words. The words in the statute mean the direct cause which, without the intervention of any other cause, produces death. We are referred to no decisions holding a defendant answerable in damages in a death case for failure to arrest the natural progress of accidental injuries."

In Support of Evolution—"Oh, what a cute little dolly! Does she say 'Mama, when you squeeze her?'" "Naw. My dolly's a modern dolly. When you squeeze her she says 'Oh Boy.'"

MEDICAL STRAWS

By THE EDITOR

Experience is fallacious and judgment difficult

Has It?—"It is in the early detection of possible communicable conditions," says the California State Board of Health Weekly Bulletin, "that the value of the *teacher* has often been underestimated."

Every physician deplores his limitations in this difficult phase of diagnosis. We doubt the possibility of "underestimating" the teacher's diagnostic ability.

Why Babies Die—"More than 100,000 of the 250,000 children less than one year old who die every year in the United States die from causes connected with their birth," says the United States Public Health Service. "The need," it adds, "for further study and investigation of these causes is urgent."

MEDICAL science knows no country, no creed, no politics, and in general no personal advantage. The underlying motive is truth, which may be applied to the benefit of mankind. Whatever the offshoots from this development, it must be recognized that the fundamental purpose is honest, dignified, and indispensable.—Henry B. Favill.

PREVENTIVE medical practice—pre-clinical medicine, if you please—applies to all supposedly well individuals. Doctors should be leaders and undergo health examinations personally.—Long Island Medical Journal.

How Can They Give It?—"United States Comptroller General McCarl of Washington has rendered a decision that, in the case of illness of a consular clerk, a certificate by a Christian Science practitioner is sufficient to secure leave of absence."

66 **ACCORDING** to a recent issue of Better Times, the people of the United States spend annually 65 cents per capita on coffins, and 11 cents on health service."

THE man of delicate constitution who has had to watch his health from childhood, and who calls in a doctor every time he sneezes, stands in perhaps the smallest need of annual overhauling. In the ordinary course of events he is likely to receive all the medical scrutiny he requires.—Long Island Medical Journal.

BY ALL means we must educate the patient in the ways of the doctor, but let us not forget the equally important fact that the doctor must also be educated in the ways of the patient.—Medical Pocket Quarterly.

IN THE hands of the charlatan, people in general are nothing but absurd puppets, and their emotions are the strings by which they are worked.—Colorado Medicine.

HE WHO plants an oak tree and he who plants an idea must love the future more than the present, for both are of very slow growth.—Journal Social Hygiene.

MEN'S passions operate variously, and appear in different kinds of actions, according as they are more or less rectified and swayed by reason.—Joseph Addison.

Will California Ever Do This?—"The Cincinnati

Board of Education enforces a vaccination rule as a prerequisite to school enrollment, with the result that last year there was not a single case of smallpox among the school children of the city."

"Drink Deeper"—One may as well not know a thing at all as to know it imperfectly. To know a little of anything gives neither satisfaction nor credit, but often brings disgrace and ridicule.—Earl of Chesterfield.

IT IS extraordinarily difficult to establish the efficacy of a therapeutic agent.—C. A. L. Binger.

66 **THE** modern Moliere, Bernard Shaw," says Riesman (A. M. A. Bulletin) "has sensed our foibles, and has not spared the rod, to the delectation of those who are ignorant of the great advances made by medicine in recent times. However, we need the Moliere and the Shaws as counter-irritants, lest we wax proud and become unmindful of our deficiencies."

'Tis a Pity Some Are Not Sent Younger—Most men go out better than when they come in. Prisons are often said never to have done anyone any good, but that is not generally true. Of course, having been in prison is a social handicap, but most men leave better off mentally and physically than when they came in. Regular food, regular hours, hygienic conditions, and regular work have given them better health—as to morals we cannot say.—Warden Johnson, San Quentin Prison.

Is Poverty Increasing?—During 1922, 7,000,000 people were treated, with a total of 30,000,000 visits in over 4000 "free clinics."—Editorial Boston Medical and Surgical Journal.

This Is Not New—Perhaps You Know the Author?—The strange thing about knowledge is this: Every new discovery but opens up wider regions to be conquered. The less a man knows, the less for him there is to be known. The more a man knows, the more there is for him to know. Wise men no longer measure learning by what they know, but by what their learning shows them they do not know. The Unknown is the only region that is increased, the only region that is not decreased, by discovery.

IF WE step down a little from our pedestal, we shall surely come to a better understanding with our fellow-citizens—David Riesman (A. M. A. Bulletin).

MY FUNCTION as a physician is not discharged when I say to a solicitous client, "There is nothing the matter with you"; unless that opinion is fully accepted. And if my patient continues to believe there is something the matter with him, there is something the matter with him and my function has not been fulfilled until I have made him see, as I see, that he is not in jeopardy.—Henry B. Favill, M. D.

A Country Doctor Praises Specialists—The specialists I have called and who have assisted me have always done their best and have treated me and my people faithfully and ethically, and I trust that this has been your experience. The welfare of the patient is ever paramount, and it certainly is to the best interests of our patients if quickly, cheerfully and confidently we take them to those places and to the men who, better than anyone else, can operate and treat, and where the hopes for recovery are the best.—Austin Flint (Iowa Medical Journal).

Hospital sterilizing safety in your own surgery

The risk in using partly sterilized goods is as great in a small hospital or clinic as in a large institution. In either place the danger from infection is too large to be neglected.

It more than pays to have a wide margin of safety on your side, no matter where you operate.

The CASTLE 1336 combination gives you that protection. It has a 10x20" autoclave, eight gallon tanks for hot and cold water with a filter, and a 19" instrument sterilizer. It is ideal for community hospitals, clinics, and small surgeries.

BOOK REVIEWS

This column is conducted solely in the interests of California and Western Medicine readers. Critical comment, favorable and unfavorable, purely from the standpoint of the interests of the medical reader, will be made about books selected from the larger number acknowledged in the Books Received column. The advertising columns are open to book publishers who wish to make additional statements about their publications.

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1924. Cloth. Price, postpaid, \$1. Pp. 82. Chicago: American Medical Association, 1925.

This volume contains the reports of the Council on Pharmacy and Chemistry that have been adopted and authorized for publication during 1924. Some of these reports have appeared in The Journal of the American Medical Association. Others are now published for the first time.

The annual volumes of the "Council Reports" may be looked on as the companion volumes to New and Non-official Remedies. While the latter contains the medicinal preparations that are found acceptable, the reports contain the reasons why certain products were not accepted. Thus the present volume contains reports on the following products which the Council denied admission to New and Nonofficial Remedies: Aolan; Aspatol; Atussin; Pepto-proteasi; Paraganglina Vassale; Fosfoplasmina; Asmoganglina and Endo-Ovarina Tablets; Borosodine; Carsinol; Colodine and Colobromidine; Ferrasin; Glyeuthymenol; Hoyt's Gluten Flakes; Iodeol; Loefflund's Food Maltose; Mistura Creosote Comp. (Killgore's) and Tablets Cascara Comp. (Killgore's); Neo-Riodine; Nicomors; Peptone Solution for Hypodermatic Use (Armour); Pixalbol; "P-O-4"; Pollantin; Promonta; Pruritus Vaccine Treatment-Lederle (Montague Method); Restor-Vin; Some "Mixed" Vaccines of G. H. Sherman and Tersul Hiller.

The volume also contains reports on products which were included in former editions of New and Nonofficial Remedies but which will not appear in the 1925 edition because they were found ineligible for further recognition. Among these are polyvalent antipneumococcal serum, colon bacillus vaccine, gonococcus serum and gonococcus vaccine.

The volume contains a number of reports of a general nature; for instance, a report on the therapeutic value of benzyl benzoate; a report on anaphylaxis produced by thromboplastic substances and a report on the therapeutic use of digitalis.

Physicians who keep fully informed in regard to the value of proprietary remedies will wish to own this book.

Hunting With the Bow & Arrow

BY DR. SAXTON POPE

An attractive volume containing 256 pages and 50 illustrations, printed on art paper, substantially bound in buckram with stiff board covers and crash russet sides appropriate to outdoors. There are sixteen chapters, each dealing with some phase of archery. They describe the Indian methods of using the bow; how to make bows and arrows; the ballistics of archery; how to shoot; hunting small game — the coon, fox, coyote — and relate experiences in killing deer, mountain lion and bear with bow and arrow. The illustrations are from photographs taken in the field and give the reader a clear picture of the hunting scenes. It is a book that every archer and sportsman should have in his library and should be read by all who love this fair sport and adventure.

Racine, Wis.

Do You Know the Answer?—It is a strange thing that some doctors who are delinquent in their dues to medical societies are never delinquent in their dues to country clubs. A man will pay from \$1 to \$500 for membership in a country club, and from \$75 to \$200 each year in dues, and never bat an eye and never fail to have his payment in on time, but he will neglect to pay \$10 or \$15 as dues to his medical society, get mad at the secretary for being solicited for the dues, and finally threaten to withdraw from the society because he thinks he is mistreated. . . . Medical societies must have not only the moral, but financial support of doctors in order to accomplish their purposes. The money we put into medical societies is insignificant, as compared to the money that we spend in a hundred other ways without getting a tenth as much return. We ought to be ashamed of ourselves for any negligence in helping support medical societies by prompt payment of dues, and we deserve penalization if we do not accept the obligation and live up to it."—*Journal Indiana Medical Association.*

A Fact Frequently Overlooked—We are convinced that health examinations in our public schools are valuable in direct proportion to not only the ability of the examiner who makes them, but the care exercised in their examination. However, all parents should be impressed with the idea that they make very serious mistakes if they always accept and rely upon the findings of a public school examination as a guide as to what to do about the health of their children.—*The Journal of the Indiana State Medical Association, March, 1925, Editorial.*

When Newspapers Adhere to Their Ethics—With national advertisers out after the "nostrum advertising" and a number of newspapers and periodicals already closing their columns to them, the day is approaching when fake health "cures" should cease to be a problem—at least to the extent it is today.—*Editorial, Ohio State Medical Journal.*

Physicians & Surgeons Institute of PHYSIO-THERAPY

*Limited to the
Treatment of Ambulatory Private Cases under Strictest
Medical Supervision*

226 Haight Street, San Francisco

Phone Park 6156

We maintain unusual facilities of scientifically proven efficiency for the relief of suffering. We execute physicians' orders in the treatment of the following chronic indications:

General Debility,
Protracted
Convalescence,
Disorders of
Nutrition,
the Alimentary
Tract,
Muscle Atrophy
Ankylosed Joints

Functional
Disturbances
of the
Nervous System,
Cardio-Vascular-
Renal
Disorders,
and
Defects of Physical
Development

All approved forms of *Hydrotherapy*,—coupled where indicated with *Nauheim*,—*Hydro-Electric*,—*Radio Active Clay*,—*Calcic Carbonate*,—*Magnesia Carbonate* and *Sulphate Baths*,—*Radium Emanatorium*. Modern modifications of *Zander Apparatus*, *Massage* and *Manipulations*. *Electro-Therapy*, *Thermo-Penetration*, *Actino-Therapy*, the *Bergonie Treatment for Obesity*, *Proctoclysis*, *Corrective Gymnastics* and the application of tabulated *Physical Efficiency Tests*.

*Service rendered only to patients referred to us by
the Medical Profession. No other
cases accepted*

DOCTOR—Our Institute endeavors to meet a great and necessary co-operative role with the Physicians and Surgeons of San Francisco and Bay cities, in their fight with intractable morbid conditions. Our Institute is simply a unique and efficient therapeutic agent, available to all reputable physicians who want to retain their patients, but desire to place them in the hands of specially trained technicians who are equipped with the required modern therapeutic appliances and experience, and who make a specialty of coping with conditions described.

If its for the physician, hospital or sickroom, we have it

Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in—

ALQUA WATER contains the alkaline salts found normally in the human body. Physicians will find it invaluable where alkaline treatment is indicated. Not only is it very effective in the treatment of most acute and chronic diseases caused or accompanied by acidosis, but it is an ideal preventive, in that it neutralizes destructive acid by-products in the system.

GLACIER SPRING WATER with which Alqua is prepared, originates in the upper glaciers of Mt. Shasta, California, U. S. A., (Elevation 14,442 ft.) Its great purity without artificial treatment, renders it especially suitable for affinitization with the added salts, thus forming a combination that is remarkable as an alkaline water. Glacier water is released from the earth at Shasta Springs where it is put into block-tin lined carriers and transported to the Company's laboratory where the alkaline salts are scientifically added under the directions of an expert chemist, thereby creating, through the united efforts of science and nature, the wonderful medicinal virtues of Alqua Water. ASK YOUR PHYSICIAN ABOUT IT. ALQUA MEDICINAL WATER CO.

At All Druggists

The Engeln Diatherm

An Established Aid in Therapy

AFTER an extensive study of the needs of the busy Physician we have developed The Engeln Mobile Diatherm as the first real progression from the conventional trend of design. Although capable of continuous heavy-duty operation, this sturdy unit possesses all of the ease of operation and delicacy of control for which Engeln Equipments are famous. ~ ~ ~

The white Duco and natural walnut finish make an attractive contrast to the black crystal lacquer panels and polished nickel hardware, while the cushion-tired wheels permit free and noiseless mobility.

AT YOUR REQUEST—

WE WILL be very glad to send you a copy of our new publication, "The Modern Science of Diathermy." This booklet is especially interesting because it represents the experiences of eight or nine of the best known authorities on the subject, abstracted from their original articles. The theory of Diathermy, as well as some of the numerous conditions in which Diathermy is indicated, is very fully explained. This method of compilation gives you the story of Diathermy in the Doctors' own words and also presents a variety of ideas and applications. Just mail your request to Department D, East 30th and Superior Ave. and we will be glad to mail your copy immediately.

The Management of an Infant's Diet

Mellin's Food—A Milk Modifier

Theory, study and observation in relation to the artificial feeding of infants support the principles that have kept Mellin's Food conspicuously in the foreground ever since the earliest efforts to consider infants' nutrition from a scientific basis.

Mellin's Food has proved itself over and over again as a most valuable aid to the physician in directing the preparation of nourishment for the baby deprived of human milk.

Mellin's Food Co., 177 State Street Boston, Mass.

FRENCH HOSPITAL

French Mutual Benevolent Society, founded in 1851

Geary Street at Fifth Avenue
San Francisco, Calif.

General hospital of 220 beds, accepting all cases except mental diseases. Built upon the pavilion plan, allowing large air space for each patient. The buildings occupy a full city block, built around a beautiful central court. Aseptic, operating and delivery rooms. Complete X-Ray Department with portable apparatus. FOR SALE—AS I DESIRE TO GIVE UP GENERAL PRACTICE AND devote myself to special work, I offer for sale my practice together with the Cloverdale Hospital. This is a fine location for an active man doing general medical and surgical practice. For information write or call, W. C. Shipley, Cloverdale, California.

SITUATIONS WANTED—Salaried Appointments for Class A physicians in all branches of the Medical Profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan, Chicago. Established 1896. Member The Chicago Association of Commerce.

FOR SALE—PRIVATE HOME SANITARIUM IN SAN FRANCISCO, beautiful residence completely equipped for private sanitarium. Earning \$6000 a year; can be doubled. Suitable for doctor or nurse. Large ward for ten persons; sun porches and private rooms. Garage large enough for ambulance to drive in. Centrally located. Detached house; key lot; large garden. Price reasonable. Terms arranged. Address A. M. C., care of CALIFORNIA AND WESTERN MEDICINE.

WANTED—INDUSTRIAL APPOINTMENT OR ASSOCIATION WITH A Group or Surgeon in California. Graduate of Class A school; 10 years' experience in Industrial Surgery. Now holding a responsible industrial position. Desire to change. Address Dr. 525, CALIFORNIA AND WESTERN MEDICINE.

POSITION WANTED—WOMAN PHYSICIAN, PATHOLOGIST, ANESTHETIST, desires position, institutional or with group. Address Box No. 500, CALIFORNIA AND WESTERN MEDICINE.

FOR SALE—A SEVEN-ROOM RUSTIC BUNGALOW, BEN LOMOND, Santa Cruz Mountains, one block from highway. About three acres gently sloping virgin soil with fourteen magnificent oak trees and circular spruce grove, and many other varieties of trees and shrubs. Love Creek forms one of the boundaries, while San Lorenzo River is only one block distant, and the air of seclusion and privacy belie the fact that it is near Post Office, Stores, Highway and S. P. Station. Price \$8000. Allen & Co. Country Dept., 168 Sutter street, San Francisco.

SITUATION WANTED—INTERNIST, 38, MARRIED, PROTESTANT, desires association with strictly ethical group. 1907 Michigan graduate, 2-year interne service in industrial hospital; 10 years general practice and four years in internal medicine and X-Ray in West. For past 1½ years engaged in post-graduate study in foremost teaching medical clinic in the East. Have had unusual training in clinical medicine, clinical pathology and fundamental diagnostic procedures including blood chemistry and electrocardiography. Only high grade offers will be considered. Address Dr. 530, CALIFORNIA AND WESTERN MEDICINE.

SPLENDID OPENING FOR PHYSICIAN IN A CITY IN STANISLAUS County, California; three thousand population, approximately one hundred miles from San Francisco. Will sell or lease office and sanitarium in heart of business district. Unusual opportunity for physician to locate at present time. Very attractive proposition. Do not wait. Write Box 540, CALIFORNIA AND WESTERN MEDICINE.

OFFICES FOR RENT—MODERN OFFICES FOR DOCTORS ONLY, FOR rent in my new building, corner 40th and Broadway, Oakland. Steam heat, hot water, janitor service. For particulars write or see C. K. Brower, 4015 Broadway, Oakland, California.

FOR SALE—BEAUTIFUL HOME SITE ON HIGHWAY BETWEEN BEN Lomond and Brookdale. Wonderful view. Part cleared and part wooded. Two and one-half acres. Price \$1800; terms. Address Dr. W. A. Phillips, Ben Lomond, Calif.

Does "Education" Replace Superstition? Apparently Not—According to the health officer of Illinois, Doctor Rawlings found that from 2 to 60 per cent of high school students among over 1500 questioned in four states, believe in various superstitions that have nothing but folk-lore to support them. About one in five high school students believe that "mad stone" will prevent hydrophobia; 26 per cent believe that warts may be removed by charms and other hocus-pocus; 60 per cent believe that malaria is caused by drinking stagnant water, and 23 per cent believe that a horse hair left in a trough of water will grow into a snake. There were other beliefs even more preposterous than these. This, after decades of "health education" from conception to death, is enough to discourage the average person interested in the welfare of his fellow-men.

ACIDOSIS

By some investigators ACIDOSIS has been designated as a diminution of the alkalinity in the blood; by some as an excess of acid in the blood; by others as a lessening of reserve supply of fixed bases in the blood.

If the acid combining power of the blood is impaired BY A LACK of the alkalies, sodium bicarbonate and sodium phosphate, and may be built up by the process of food ingestion, *may we ask* attention to CALSO WATER, which is rich in the potential alkalies.

The Consequences of Carelessness—There are few that would disagree with the statement that, if every properly educated and licensed physician did his professional work as well as he knows how to perform it, the agents of the pseudo-medical cults would disappear in less than a year. It is the crowded office hours' apparent necessities that leads practitioners to the pathways of professional carelessness. —Edward Beardsley (New York Medical Journal).

ALUM ROCK SANATORIUM

FOR THE TREATMENT OF TUBERCULOSIS IN ALL ITS FORMS

The Sanatorium adjoins Alum Rock in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

A Perfect Example. . . .

A model for its size—The laundry at The Martins Ferry Hospital, Martins Ferry, Ohio

of the small hospital laundry

Glance again at the picture—note the bright, airy room; the compact arrangement of the equipment; the completeness of the installation. Here is a perfect example of the modern small hospital laundry—the laundry of The Martins Ferry Hospital, Martins Ferry, Ohio.

This model plant occupies a separate building, entirely detached from the hospital itself. The equipment consists of a Solid Head, all Brass Washer, a Vertical Motor Driven Extractor, a Return Apron Flat Work Ironer, two Prim Presses, an ironing board, a folding table, and a junior Drying Tumbler. Three employees handle all of the washing and ironing for the hospital, which at present has sixty beds. However, the machinery is capable of caring for the needs of a seventy-five bed hospital.

The Martins Ferry Hospital laundry was planned and installed by engineers of The American Laundry Machinery Company, and "American" equipment was used throughout. For complete details about this or other laundry installations, simply write. A corps of laundry experts, maintained by The American Laundry Machinery Company, will be glad to give you the benefit of their experience, without obligation on your part.

Hanovia Quartz Lamps

ALPINE SUN KROMAYER

Original Pioneers in 1905

You cannot mistake a HANOVIA QUARTZ LAMP for any other.

These who take pride in their quartz lamps value this distinction. It is assembled by skilled workmen who have devoted years in the HANOVIA Plant to the creation of a fine mechanical work.

These features with the entire quartz mercury anode type of burners, which give the maximum intensity of Ultra Violet Rays, should be strongly considered.

For literature of its use in Eye, Ear, Nose and Throat conditions, Hay Fever, Asthma, Tetany, Rickets, Tuberculosis, Dermatology, Gynecology, etc.,

"REQUEST SET 47."

A GOOD MOVE IN THE TREATMENT OF CONSTIPATION

ZED

Once the sufferer from chronic constipation is weaned away from the nightly pill habit, it is easier to make him see the importance of *natural* eliminative measures.

Show a patient that his daily diet can, and should, overcome intestinal stasis and he is quite willing to cooperate. Specify ZED as part of the dietetic regimen and you will find him doubly willing.

For ZED is something that most health-biscuits are not: *really tasteful!* A scientific blend of whole wheat, bran, milk, natural fruit and vegetable extracts—ZED has not forgotten that the first function of food is to appeal to the taste-nerves. ZED does—most emphatically!

To enable you to prove this to your own satisfaction, as well as that of your patients, we will be glad to send a regular sized package of ZED for trial purposes.

Zed Corporation • San Francisco

*Every grocer has, or can easily get, ZED
Biscuits for your patients*

TRUTH ABOUT MEDICINES

New and Non-official Remedies

(Abstracts from reports of Council on Pharmacy and Chemistry, A. M. A.)

Note—These do not represent all of the actions of the Council, but they do represent those remedies manufactured by firms who co-operate with California and Western Medicine in its advertising columns, and thereby with the physicians in California.

In addition to the articles enumerated in our last report, the following have been accepted:

Abbott Laboratories—Butesin Picrate Dusting Powder.

Eli Lilly & Co.—Hletin (Insulin—Lilly) U-80, 10 cc.

Parke, Davis & Co.—Desiccated Parathyroid Gland (P. D. & Co.); Cauliflower Protein Extract Diagnostic (P. D. & Co.); Lentil Protein Extract Diagnostic (P. D. & Co.); Friedlander Bacillus Protein Extract Diagnostic (P. D. & Co.); Micrococcus Tetragenus Protein Extract Diagnostic (P. D. & Co.); Streptococcus Hemolytic Protein Extract Diagnostic (P. D. & Co.); Streptococcus Non-Hemolytic Protein Extract Diagnostic (P. D. & Co.); Paratyphoid A Protein Extract Diagnostic (P. D. & Co.); Paratyphoid B Protein Extract Diagnostic (P. D. & Co.); Pine Pollen Protein Extract Diagnostic (P. D. & Co.); Apricot Protein Extract Diagnostic (P. D. & Co.); Yellow Daisy Pollen Protein Diagnostic (P. D. & Co.); Ox-Eye Daisy Pollen Protein Diagnostic (P. D. & Co.); and Oak Pollen Protein Extracts Diagnostic (P. D. & Co.).

E. R. Squibb & Sons—Insulin (Squibb), 40 Units, 5 cc.; Bean (Kidney) Allergens (Squibb); Cauliflower Allergens (Squibb); Frog's Legs Allergens (Squibb); Daisy Pollen Allergens (Squibb); Bacillus Acne Allergens (Squibb); Bacillus Friedlander Allergens (Squibb).

Squibbs Liquid Petrolatum With Agar—A mixture composed of liquid petrolatum (Squibb) heavy (California) 50 cc.; agar 1.5 gm.; sodium benzoate, 0.1 gm.; acacia, glcerin, and water sufficient to make 100 cc. Squibb's liquid petrolatum with agar, has the action of liquid petrolatum. It is claimed that the agar, by adding bland bulk to the bowel contents, stimulates peristalsis in a normal way, and that the combination of liquid petro-

latum with agar mixes readily with the feces and softens them.—E. R. Squibb & Sons, New York.

Mercurosal Ampules 0.1 Gm.—Each ampule contains mercurosal (New and Non-official Remedies, 1924, p. 207), 0.1 gm. in 5 cc. of distilled water containing 0.1 per cent of sodium citrate.—Parke, Davis & Co., Detroit (Journal A. M. A., March 7, 1925, p. 751).

A chap was arrested for assault and battery and brought before the judge.

Judge (to prisoner)—“What is your name, your occupation, and what are you charged with?”

Prisoner—“My name is Sparks, I am an electrician, and I am charged with battery.”

Judge—“Officer, put this guy in a dry cell.”

The Doctor's Burden

(With apologies to Kipling)

Take up the Doctor's burden—
Have done with easy days—
The lightly proffered laurel,
The easy ungrudged praise.
Comes now to search your manhood
Through all the future years,
Cold, edged with dear-bought wisdom,
The judgment of your peers!

—T. V. Smith.

“Excuse me,” she said, as she entered the country editor's office. “You editors are supposed to know everything. How should I treat sick bees?”

“With respect,” was the answer.

Some Religions Make Even the License Unnecessary—“A physician's conduct toward his patient, and also toward the public health, may be so harmful, disgraceful, diabolical or infamous as to make his continuance in the profession a public wrong,” says H. E. Kelly, member of the Chicago Bar, “yet no other ground than that of unprofessional or dishonorable conduct may enable the authorities to revoke such a physician's license. This ground ought to be stated in the law, so that it may be used for the protection of the people in cases in which a specific ground is not stated because the particular offensive acts are unusual, entirely unforeseen, or as a matter of expediency too many subjects of detail to be specifically enumerated in the statute.”

HOSPITAL FOR CHILDREN AND TRAINING SCHOOL FOR NURSES

A general hospital of 275 beds for women and children. Thirty beds for maternity patients in a separate building, newly equipped.

Complete services of all kinds for women and children. Infant feeding a specialty.

House staff consists of three resident physicians and eight internes.

Accredited by the Council on Medical Education and Hospitals of the American Medical Association.

Institutional member of League for the Conservation of Public Health.

The oldest school of nursing in the West.

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of

them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) \$45.00 per week and upward.

*The
Findings of Medical
Research are Embodied in
Victor
Quartz Lamps*

AS soon as it was definitely established by medical and biologic research that air-cooled and water-cooled quartz lamps emit ultra-violet rays of markedly different therapeutic properties, the Victor organization proceeded to develop lamps which would enable hospitals and physicians in general practice to apply ultra-violet rays with the precision demanded in modern therapy. Victor air-cooled and water-cooled quartz lamps have therefore been generally accepted as the most practical devices of their kind for the intelligent treatment of many conditions common to every practice.

PHYSICIAN AND SURGEON
1104.9 PACIFIC SOUTHWEST BUILDING
FRESNO, CALIFORNIA

March 9, 1925.

Mr. L. B. Miller,
Victor X-Ray Corp.,
254 Sutter St.,
San Francisco, Calif.

Dear Mr. Miller:

Enclosed you will find a cashier's check for \$874.28,
covering the items on the attached list.

I wish to take this occasion to express my appreciation of the uniform courtesy and excellent service which I have received from every member of the Victor X-Ray Corporation with whom I have had dealings. My first experience with the Victor organization and its apparatus was in the x-ray laboratory of the University of Pennsylvania, where I studied under Dr. Henry Pancoast, Professor of Roentgenology. From that time on, the service rendered me by your representatives has been all that anyone could desire, and I have never purchased an article from your company which was in any way misrepresented. I feel, therefore, that any physician who is acquainted with the character of the service rendered by Victor in this vicinity would be exceedingly unwise to trust his business in any other hands.

Your local representative has done everything in his power to assist me with my apparatus and to maintain the high standards of the company he represents.

Very truly yours,

Edwin L. Mott.

THE MIM COMPANY,
637 Woodward Bldg., Washington, D. C.

This Sign Is Your Protection

It assures you that the dealer who displays it is reliable and that he distributes a product of unquestioned merit.

By the way, has it ever occurred to you that your outlay for equipment is the sum of two components, a relatively **LARGE** amount representing the minimum cost from any source, plus a relatively **SMALL** amount representing refinements in quality, convenience, and service? Have you also reflected that what the smaller amount purchases is vastly more important to you than what the larger amount covers?

You are therefore thwarting your own interests if you are swayed by price alone, especially when a very slight additional outlay will equip your office with

ALBATROSS METAL FURNITURE

the product of a responsible firm, absolutely guaranteed without limit as to time against defects in materials or workmanship, and sold by the most reliable and enterprising dealers everywhere.

Remember, the annoyance and inconvenience attendant upon using equipment poorly constructed and incorrectly designed persist and grow from day to day. Remember, too, that in their stead at a very moderate increase in the initial cost you may have the pleasure derived from the convenience and attractiveness of **ALBATROSS FURNITURE** and this, too, will be enhanced rather than diminished with the lapse of time.

This Sign Is Also Your Protection

It appears on every piece of Albatross equipment, identifies it as an Albatross product and therefore insures its satisfactory performance.

Announcing a Round Trip Rate to Yosemite and the Mariposa Grove of Big Trees in connection with the Annual Convention of the Cali- fornia Medical Association

The Yosemite Park & Curry Company takes pleasure in announcing arrangements whereby, in connection with the California Medical Association Convention, you can buy your tickets direct from home to include your round trip transportation to and from Camp Curry or Yosemite Lodge in Yosemite Valley, and the wonderful trip to the world-famous Mariposa Grove of Big Trees, the oldest living objects in the world.

Rates for complete round trip transportation are as follows:

San Francisco	to Yosemite and return, including auto trip to Mariposa Grove of Big Trees.....	\$33.25
Los Angeles	to Yosemite and return, including auto trip to Mariposa Grove of Big Trees.....	\$42.25

Corresponding fares are available from other points in California

Be Sure to Visit the Big Trees

The Nutritive Properties of Natural Cow's Milk

are retained in

KLIM

Analysis of KLIM

POWDERED WHOLE MILK

	Dry	Liquid *
BUTTERFAT	28.00%	3.33%
CASEIN	21.28%	2.53%
ALBUMIN	5.46%	.65%
LACTOSE	38.00%	4.53%
ASH	5.76%	.69%
WATER	1.50%	88.27%
CALORIES (per ounce)	149.	18.

* 4½ Ounces to a quart of water

KLIM is completely soluble in water of any temperature

When Used in Infant Feeding

Reliquified KLIM at normal strength has the same analysis and caloric value as natural whole cow's milk and is subject to the same modifications when used in infant feeding

Recognizing the importance of scientific control, all contact with the laity is predicated on the policy that KLIM be used in infant feeding only according to a physician's formula.

MILK atomized into filtered air sufficiently warm to cause instantaneous evaporation of the water—is KLIM.

The rapid evaporation of the water so cools the milk particles as to prevent over-heating—evidenced by the fact that in KLIM

The albumin is not coagulated

The lactose is not caramelized

The vitaminic potency is not diminished (see Dutcher and Cavanaugh--June, 1923, ed. American Journal Diseases of Children).

The enzymic reactions are normal

The powder is completely soluble

Given, also, simplicity of preparation, absolute safety and superior digestibility, the physician has at his command a worthy substitute when breast milk is insufficient

*Literature and samples
sent promptly upon request*

Fruits for Non Sugar Patients

Fruits may now be prescribed for non-sugar diets, even when fresh fruits are not available.

Nutradiet canned fruits are the best quality fruits—the famous S & W standard of quality—packed *without* syrup.

Instead of sugar, Nutradiet fruits are canned in sterile water or natural juice. And a part of the natural sugar passes into the water after canning, leaving Nutradiet fruits with even less sugar than the fresh fruit.

Chemical analyses of Nutradiet fruits will be sent gladly on request. Also list of grocers where Nutradiet fruits may be purchased.

[[Nutradiet salt-free vegetables
are packed without salt or sugar.]]

PREVENT HAY FEVER

Pollen Allergen Solutions Squibb

NOW is the time to immunize your Hay Fever patients against their annual affliction. Pollen Allergen Solutions Squibb are used for the prophylaxis and treatment of Hay Fever and other pathologic conditions due to pollen sensitization. Treatment should commence several weeks before the expected onset of the usual seasonal occurrence.

SQUIBB'S DIAGNOSTIC POLLEN ALLERGEN SOLUTIONS afford the means of determining the offending pollens as a guide for treatment. The prophylactic treatment consists of graduated doses of the glycerol solutions of the pollen proteins. Complete sets of these in graduated doses and in 5 Cc. vials are offered by the Squibb Laboratories as Pollen Allergen Solutions Squibb.

Write us direct for special information concerning the use of Diagnostic Allergens Squibb and Pollen Allergen Solutions Squibb for the prevention and treatment of Hay Fever and allied conditions.

INFANT DIET

CONTR THE INFANT'S DIET

The physician knows the requirements of the individual baby—he alone is fitted to prescribe and to regulate the infant's diet.

His prescribing of the proper food, based upon the infant's nutritional requirements, is of far more advantage to the infant than a printed set of rules on the label or bottle.

The trained physician eliminates guesswork. He gives the mother a feeding formula and expects her to follow his directions.

The physician who prescribes MEAD'S Infant Diet Materials knows his instructions will be followed to the letter. There are no directions on the packages to conflict with his formula for each individual baby.

MEAD'S DEXTRI-MALTOSE

Cow's Milk and Water

meet the demands of the average well baby

MEAD'S CASEC

and

MEAD'S POWDERED PROTEIN MILK

are very satisfactory in treating Summer (Fermentative) Diarrhea

Samples of these products and literature sent on request

The Mead Policy

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes her feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians

Are You Reading **BETTER HEALTH?**

MOST newspapers, magazines and publications of every sort are now featuring alleged Health Education, Public Health, and even the practice of medicine by mail, as one of their functions. Of the few magazines that are producing worthwhile informative publicity in this field, **BETTER HEALTH** is the oldest. This magazine is owned and conducted by physicians and devoted entirely to improving the knowledge of the general public on matters pertaining to the promotion, conservation and protection of health; and it is one of the exceedingly small number presenting sound and authoritative health information of the same general type that the physician gives to his patients and friends. A copy should be on the table in your reception room at all times. Every physician, at least in the Western States, should be a subscriber to **BETTER HEALTH Magazine**. It needs your support for many and obvious reasons. If you are not a subscriber, please cut out the coupon and mail it at once. Suggest to your patients that they also subscribe.

To **BETTER HEALTH**, Balboa Building, San Francisco

Please send me **BETTER HEALTH**, the monthly magazine with the Daily Health Service, beginning with the June issue, 1925. Upon receipt of magazine and bill, I will send you \$3, payment in full, for one year's subscription.

THE TREND IN CLINICAL MEDICINE
IS TOWARD THE MORE EXTENSIVE EMPLOYMENT OF

Tetanus Antitoxin FOR CURATIVE PURPOSES

ANTITETANIC SERUM was at one time generally regarded as an efficient prophylactic rather than as a curative agent. But there is an unmistakable trend nowadays toward the use of antitetanic serum as a specific curative agent as well.

A prominent surgeon writes us: "A great deal of the pessimism in the use of serum for curative purposes is perhaps because it is not given by the best route and in large enough doses. My statistics, as far as I have gone at present, show that in cases that have received a dose of 30,000 units by vein the mortality is only 3 per cent. It will probably be much better than this if one should cut down to the cases that have received this dose in the first three days of the tetanus symptoms."

Certain it is that early diagnosis and large therapeutic doses have materially lowered the mortality.

TETANUS ANTITOXIN, P. D. & CO., commends itself to the discriminating physician because of its high refinement, small bulk, and gratifying reliability.

Our Tetanus Toxin is of such strength and uniformity that healthy young horses under treatment with it, consistently produce a native antitetanic serum of relatively high potency.

Then, our methods of concentration have been developed to such a point that the globulin resulting from this native serum represents Tetanus Antitoxin of the highest quality, chemically and biologically.

Finally, our syringe package, fitted with an improved plunger, is proving decidedly satisfactory.

Requests for literature are always welcomed.

ILETIN INSULIN, LILLY

*Pure · Stable
Constant in Unitage*

Iletin (Insulin, Lilly) is supplied in containers of two sizes: 5 c.c. vials and 10 c.c. vials. Both the 5 c.c. and 10 c.c. vials bear the same designation: U-10, U-20 and U-40.

To distinguish between the two sizes it will be necessary, for example, to order as U-10 5 c.c. vials or U-10-10 c.c. vials.

In absence of specifications as to size wanted, the 5 c.c. vials will be supplied.

PITUITARY EXTRACT LILLY

Pure · Stable · Uniform in Strength

Purity—This extract contains the active principle of the posterior lobe of the pituitary gland in a state of purity not attained heretofore on a commercial scale.

Stability—It will remain active over a long period. Test lots have been boiled with but little loss of activity.

Uniformity—Special methods have been devised for bringing each lot to the same standard of strength.

Pituitary Extract, Lilly, is supplied in two strengths, obstetrical and surgical; order as follows:

No. 117—Obstetrical 1-2 c.c. Ampoules

No. 118—Obstetrical 1 c.c. Ampoules

No. 119—Surgical 1 c.c. Ampoules

These ampoules are packed six in a box, each in an individual carton.

Write for additional information.

All Lilly Products are supplied by the Drug Trade.

On Prescription Only

PETROLAGAR is issued as follows: PETROLAGAR (Plain); PETROLAGAR (with Phenolphthalein); PETROLAGAR (Alkaline); and PETROLAGAR (Unsweetened, no sugar).

PETROLAGAR has been accepted for New and Non-official Remedies by the Council on Pharmacy and Chemistry of the American Medical Association.

Use PETROLAGER on prescription. It is not desirable to tell the patients the name of the product and advise them to buy it over the drug store counter. This only tends to self-medication and to draw the patient away from your influence.

PETROLAGER can be your most useful adjunct in the treatment of constipation. A regimen of correct diet, exercise, etc., is also indicated.

Only by keeping the patient under your influence can you effect a cure. This is the reason why advertised medicaments of any kind are obnoxious.

PETROLAGER is **your** product, Doctor, just the same as if it were compounded in the pharmacy to your special prescription. It is ethical in every sense.

It is an emulsification of 65 per cent of pure mineral oil with agar-agar. No fermentative gums are used.

Send coupon for interesting treatise on the physiology of the bowel, entitled "Habit Time." You may have a copy free, without obligation.

TRUTH ABOUT MEDICINES

New and Non-official Remedies

(Abstracts from reports of Council on Pharmacy and Chemistry, A. M. A.)

Note—These do not represent all of the actions of the Council, but they do represent those remedies manufactured by firms who co-operate with California and Western Medicine in its advertising columns, and thereby with the physicians in California.

In addition to the articles enumerated in our last report, the following have been accepted:

Cutter Laboratories—Rabies Vaccine (Semple)—Cutter.

Hynson, Westcott & Dunning—Brom-sulphalein (H. W. D); Solution Brom-sulphalein (H. W. D).

Eli Lilly & Co.—Scarlet Fever Streptococcus Antitoxin (Unconcentrated); Scarlet Fever Streptococcus Antitoxin (Concentrated).

E. R. Squibb & Sons—Lentil (Allergen-Squibb).

Butesin Picrate Dusting Powder—It is composed of butesin picrate 5 per cent and sodium stearate 95 per cent. Abbott Laboratories, Chicago.

Iron Citrate Green (P. D. & Co.)—A complex ferric ammonium citrate, containing ferric citrate equivalent to 16 per cent of iron and ammonium citrate equivalent to 8.1 per cent of ammonia. For a discussion of the actions and uses of iron preparations, see New and Non-official Remedies, 1924, p. 165. Iron citrate green (P. D. & Co.), is intended for intramuscular and hypodermic administration. Iron citrate green (P. D. & Co.) is supplied in the form of ampules containing, respectively, $\frac{1}{4}$ grain, $\frac{3}{4}$ grain and $1\frac{1}{2}$ grain of the iron citrate green (P. D. & Co.). Parke, Davis & Co., Detroit.

Allergens (Squibb)—In addition to the allergens (Squibb) previously accepted, the following have been accepted: Bacillus Acne Allergen (Squibb); Bacillus Friedlander Allergen (Squibb); Bean (Kidney) Allergen (Squibb); Cauliflower Allergen (Squibb); Daisy Pollen

(Continued on Page 686)

"Simple" Goiter

A Surprisingly Prevalent Disease,
yet One of the Easiest to Prevent.

Iodostarine Tablets afford a method
of Prevention and Treatment logi-
cally suited to your private practice.

OUT OF 3,200 SCHOOL CHILDREN affected with simple goiter in one district, 2,780 (86.9%) were cured completely and 320 more (another 10%) were greatly improved after treatment with Iodostarine Tablets. (Steinlin: *Official School Journal of St. Gall*, 1922.) In other words, 3,100 out of 3,200 or 97% of these goiters responded to treatment—a notable achievement and an indication of the effectiveness of the remedy when properly employed in correctly diagnosed cases.

For Goiter prevention, Iodostarine Tablets are being widely used by physicians and Public Health Authorities. Reports show that they are likewise highly efficient in the treatment of simple goiter of adolescence.

Bear in mind, Iodostarine Tablets contain Iodine in an organic form; are absolutely definite in strength; are stable; keep indefinitely without liberating Iodine; do not cause gastric irritation; are very palatable.

*Boxes of 50 Tablets, Each Tablet Equivalent
to 10 mgm. Iodine*

If you are not familiar with the dosages of Iodostarine Tablet administration we shall gladly send you information and, if you so desire, a complimentary supply for trial.

Announcement

The management of GRANDE VISTA SANATORIUM of Richmond, California, announce the inauguration of a unique program of reorganization and expansion that will particularly interest physicians who have contributed to the success of the institution during the past ten years of its operation, and others. An opportunity will now be offered them to become closely identified with the institution without necessarily entailing any obligation, other than their continued good will and moral support.

In order that patients may receive the best of care and treatment possible in the light of modern scientific research, every form of apparatus known to exercise therapeutic power will be installed. A new hydrotherapy department, occupational and recreative departments, heliotherapy facilities, a golf course, tennis courts, etc., are added features of this program.

A special representative will call in person and explain details to physicians only upon request.

DEPENDABILITY

Life itself is often dependent upon the strength, constancy and certainty of the beacon that guides and protects passing ships endangered in the storm. The light must never fail.

Likewise the Medical Protective Company is depended upon by the Medical and Dental professions of the United States, who for over a quarter of a century have placed their confidence in specialized service, to guide and protect them through the "storm" of malpractice action.

The expense, annoyance and loss sustained in but one suit may easily destroy the accumulation of a life time of practice.

After Diagnosis What?

Many times, doctor, in the course of your work, you are perhaps in doubt as to just what to recommend or do with a case pertaining to certain nasal disorders. We then suggest that you first try SUCTION and IRRIGATION as accomplished by

THE NICHOLS NASAL SYPHON

You will find that results will oftentimes startle you. Just try one and be convinced as thousands of members of the medical profession have been to their entire satisfaction and surprise.

D. & Co.), Group 23 (Typhoid Bacillus, Paratyphoid Bacillus A, Paratyphoid Bacillus B). Parke, Davis & Co., Detroit.

A Truth That Is Much Juggled—It is apparent from judicial decisions and statutes that courts and legislators, in using the phrase, "the practice of medicine," and generally in dealing with the healing of the sick, have in mind not a specific kind of healing or a specific remedial agent used by any particular sect or school, but the *occupation* as such in its broadest aspects; and that the thing uniformly intended to be regulated is not any particular therapeutic agent, but the entire occupation of healing the sick for hire, regardless of remedial agents or therapeutic theories.—H. E. Kelly, Attorney.

MARY'S HELP HOSPITAL

145 Guerrero Street, San Francisco

Accredited for Intern Training by the American Medical Association.

Accredited School of Nursing.

Open to All Members of the California Medical Association.

Institutional Member League for the Conservation of Public Health.

A limited general hospital of 150 beds, owned by the Archdiocese of San Francisco, and operated by the Sisters of Charity. All classes of patients are admitted except those suffering from communicable or mental diseases. The hospital was organized and incorporated in 1892. All buildings were destroyed by the fire in 1906. A complete new modern hospital was finished July 2, 1912. Mary's Help Hospital is well located, well constructed, well arranged, and well equipped for good service.

What is Nonspi?

NONSPI is an antiseptic liquid for Axillary Hyperidrosis which you can recommend to your patients with absolute confidence. It is a preparation which destroys armpit odor by removing the cause—excessive perspiration. This same perspiration, excreted elsewhere through the skin pores, gives no offense, because of better evaporation.

NONSPI has for years been used by innumerable women everywhere and is endorsed by high medical authority in America and Europe.

Physicians, surgeons and nurses find the regular use of NONSPI insures immaculate underarm hygiene and personal comfort, so essential to those who come in contact with the ill and sensitive.

To keep the armpits normally dry and absolutely odorless, NONSPI need be applied, in the average case, but twice a week.

50c a Bottle, at Toilet and Drug Counters.

Are You a Specialist?

Of course you are! You may be a "family doctor" of the good old variety—but nevertheless you are a specialist. You specialize in curing the physical [and sometimes mental] ills of humanity.

But the chances are you do not also specialize in business—investment securities—property values—collections and disbursements—the host of routine business details forced upon the attention of the professional man.

May we relieve you of the burden of those details? We are specialists. We can care for them at a lesser cost than you can yourself.

The Selection of a Physician

The selection of a physician for an operation or as a family doctor, is usually made with some care. We consult those who have employed physicians and are governed largely by their recommendations. But having selected a physician, we follow his advice. We trust him even to the extent of submitting to operations that may have serious results.

THE POINT IS, WE TRUST THE MAN
WHO KNOWS

Now, doctor, the institutions and the firms advertised in this Journal were carefully investigated before their announcements were printed here. The medicinal products were submitted to laboratory tests before they were accepted by the Council on Pharmacy and Chemistry.

On this same principle, that patients trust you about matters with which you are informed, so your publishers urge you to trust their judgment and *buy goods from the advertisers who are admitted to these pages.* Other considerations being equal, you should give your advertisers PREFERENCE because you know they are believed to be trustworthy. Don't speculate or experiment! Trust the APPROVED firms and goods.

The Hartung Hospital Silent Call Signal System

SAFE ————— SILENT ————— SIMPLE

Calling Station No. 101

Fully Guaranteed Trouble Proof

The calling station herewith illustrated shows one of the sixteen combinations that we have to offer. This station consists of the control switch with ball chain, slip connector, pull cord and pear shaped pendant attached. A slight pull on the cord illuminates a red lamp over the door of the room visible to the patient, over the door in the corridor, the red pilot lamps in Diet Kitchen and Utility Room and the lamp in the annunciator connected with that particular circuit. These lamps continue to burn until the call is answered and the control switch knob is restored to off position.

*Illustrated booklet and detailed information upon application.

As predicted at the beginning of the year, my business has doubled in amount so far this year over the same period of last year. The reason for this is without doubt in a great measure due to the service that I am enabled to give. Thirty years of experience with medical books, in every phase, including selling, manufacturing and editing, has given me the right to say that I know something of Medical Books. Let me help you solve your Medical Book problems.

Any Book Published Secured

For Small Hospitals

The TYPE "D" LAUNDRY UNIT illustrated above is especially designed. Compact, self-contained, it is economical in first cost and in operation as well—hundreds of these units have proven their merits in small hospitals from coast to coast.

The original unit consists of a washer and extractor with frame work and motor, to which can be added other machines as your requirements demand such expansion.

We shall be glad to send interesting literature to anyone interested—address our nearest office.

Heart Station

A laboratory for the investigation of Cardiac conditions.

As we are equipped with highly specialized apparatus, in particular an instrument for determining the exact angle in which the patient is being examined, we believe we are enabled to give the heart and especially the Aorta a more than ordinary accurate examination.

An outline of our routine examination is as follows:

- (I) a. History.
b. Complete Physical Examination.
c. Heart Function Tests.
d. Kidney Function Tests.
e. Vital Capacity, etc.
- (II) X-RAY EXAMINATION
a. Pictures in Frontal Position.
b. Pictures at various angles.
- (III) FLUOROSCOPIC EXAMINATION
a. Study of the comparative size and shape of the different Cardiac chambers.
b. Measurement of the Anterior-Posterior size of the heart, frequently the first part to show enlargement.
c. Orthodiagram and Cardiac Pattern—the latter to be used in checking up your own physical findings.
d. An attempt to judge the quality of the heart muscle and determine its probable efficiency and reserve power.
e. Careful measurement of the Ascending and Descending Aorta.
- (IV) ELECTROCARDIOGRAPHIC STUDY
Almost indispensable as a diagnostic aid in many Cardiac conditions.
- (V) METABOLISM TESTS, ETC.
In all cases a detailed and comprehensive report is furnished which will include diagnosis, prognosis and suggestions.
No stay in the hospital is required.
Any single test or examination can be asked for.

A GOOD MOVE IN THE TREATMENT OF CONSTIPATION

ZED

Once the sufferer from chronic constipation is weaned away from the nightly pill habit, it is easier to make him see the importance of *natural* eliminative measures.

Show a patient that his daily diet can, and should, overcome intestinal stasis and he is quite willing to cooperate. Specify ZED as part of the dietetic regimen and you will find him doubly willing.

For ZED is something that most health-biscuits are not: *really tasteful!* A scientific blend of whole wheat, bran, milk, natural fruit and vegetable extracts—ZED has not forgotten that the first function of food is to appeal to the taste-nerves. ZED does—most emphatically!

To enable you to prove this to your own satisfaction, as well as that of your patients, we will be glad to send a regular sized package of ZED for trial purposes.

These lovely twins

owe their splendid, sturdy development to LACTOGEN. They were fed right through from the first to the seventh month on this natural food for infants. Such results are normal, because LACTOGEN is a remarkably close approximation of mother's milk. Full information and a sample tin will be sent to any physician sending in this coupon.

LACTOGEN is a homogenized, scientifically desiccated, full cream cow's milk, manufactured primarily for the feeding of infants from birth to seven months of age, who, for any reason, are denied the privilege of breast feeding.

Sold only on the pre-
scription or recommen-
dation of a physician.

No feeding instructions
appear on the trade
package.

*Increasing
the
Nutritional
Yield
of
Milk—
23%*

THE protective colloidal ability of pure, plain gelatine, in preventing the curdling of milk by the enzyme rennin and hydrochloric acid of the gastric juice, is one of the most important discoveries relating to milk nutrition.

Thomas B. Downey, Ph. D., of Mellon Institute, University of Pittsburgh, has determined by standard feeding tests that 1% of pure, plain gelatine, dissolved and added to milk, increases the nutritional yield by about 23%.

Here is the most approved method of modifying baby's milk with gelatine:

Soak for ten minutes one level tablespoonful of Knox Sparkling Gelatine in $\frac{1}{2}$ cup of cold milk taken from the baby's formula; cover while soaking; then place the cup in boiling water, stirring until gelatine is fully dissolved; add this dissolved gelatine to the regular formula.

For children and adults follow the same method, but in the proportion of $\frac{1}{2}$ teaspoonful of gelatine to a glass of milk.

In infant feeding the gelatine may be added to any regular formula prescribed by the physician.

To safeguard against impurity and disturbing acidity it is essential to specify Knox Sparkling Gelatine, the Highest Quality for Health.

The physician's reference book of nutritional diets with recipes, will be sent free to any physician, upon request, if he will address the Knox Gelatine Laboratories, 417 Knox Avenue, Johnstown, N. Y.

NOTE:—From the raw material to the finished package, the family of Knox takes pride in producing the highest quality of Gelatine.

BOOKS RECEIVED

All books received are promptly acknowledged in this column. Such acknowledgment is the only return California and Western Medicine feels obligated to render in return for the courtesy of the sender. Selected books believed to be deserving of comment will be reviewed solely in the interests of our readers. Our advertising columns are open to publishers of acceptable books for such further statements as they care to make.

Gynecology for Nurses. By M. J. Seifert, M. D., Attending Surgeon and Gynecologist, Columbus Hospital, Chicago; formerly Professor of Physical Diagnosis and Anesthesiology, University of Illinois. D. Appleton & Company, 1925. New York and London.

Diseases of Children for Nurses. Including Pediatric Nursing, Infant Feeding, Therapeutic Measures Employed in Childhood, Treatment for Emergencies, Prophylaxis and Hygiene. By Robert S. McCombs, M. D., Associate in Medicine at the Philadelphia Polyclinic; Instructor of Nurses at the Children's Hospital of Philadelphia. Fifth edition, thoroughly revised; octavo of 581 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1925. Cloth, \$2.75 net.

Personal Hygiene Applied. By Jesse Feiring Williams, M. D., Professor of Physical Education, Teachers College, Columbia University, New York City. Second edition, revised; 12mo of 414 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1925. Cloth, \$2 net.

Laboratory Diagnostic Methods—Pathological, Bacteriological, Serological and Chemical. A Manual for Physicians, Medical Students and Laboratory Technicians. By John A. Kolmer, Professor of Pathology and Bacteriology in the Graduate School of Medicine of the University of Pennsylvania and Pathologist to the Medico-Chirurgical and Polyclinic Hospitals; and Fred Boerner, Associate in Bacteriology in the Graduate School of Medicine of the University of Pennsylvania. D. Appleton and Company, New York, 1925.

Collected Reprints from the George Williams Hooper Foundation for Medical Research. The Department of

Research Medicine of the University of California Medical School, San Francisco. Volume VIII, 1923-1924; Volume IX, 1924-1925.

A Compend of Gynecology. By William Houghes Wells, M. D., late Assistant Professor of Obstetrics in the Jefferson Medical College; Assistant Obstetrician in the Maternity Department of the Jefferson Medical College Hospital, etc. Fifth edition, revised and enlarged by William Benson Harer, M. D., Instructor in Obstetrics in the University of Pennsylvania. With 167 illustrations. Philadelphia: P. Blakiston's Son & Company, 1012 Walnut Street.

Clinical Features of Heart Disease. An Interpretation of the Mechanics of Diagnosis for Practitioners. By Leroy Crummer, M. D., Professor of Medicine, University of Nebraska. Introduction by Emanuel Libman, M. D., Physician to Mount Sinai Hospital; Professor of Clinical Medicine, Columbia University, N. Y. Paul B. Hoeber, Inc., New York, 1925.

Medical and Surgical Report of Roosevelt Hospital, New York. Second Series 1925, based on the work of the years 1915-1924, inclusive. Paul B. Hoeber, Inc., publishers, New York City, 1925.

Diet in Health and Disease. By Julius Freidenwald, M. D., Professor of Gastro-enterology in the University of Maryland School of Medicine, Baltimore; and John Rubrah, M. D., Professor of Diseases of Children in the University of Maryland, Baltimore. Sixth edition, thoroughly revised; octavo of 987 pages. Philadelphia and London: W. B. Saunders Company, 1925. Cloth, \$8 net.

The Health-Care of the Baby. A Handbook for Mothers and Nurses. By Louis Fischer, M. D., Attending Physician to the Willard Parker and Riverside Hospitals; Chief Attending Pediatricist to the Zion Hospital of Brooklyn, etc. Fifteenth edition, completely revised. Funk & Wagnalls Company, New York and London, 1925.

In Terms of Advertising—Dorothy, 6 years old, was used to hearing more or less shop talk at home, both her parents having been at one time in the advertising business. Last Sunday she brought home from Sunday school a Golden Text. Her mother seeing something in her hand, asked what she had. Dorothy immediately replied, with a little shrug of her shoulders, "Oh, only an ad about God."—Everybody's Magazine.

*Our Policy
gives the
utmost in
professional
protection*

Mechanical ability and experience are just as essential in making a pair of glasses, as professional ability and experience are in making the diagnosis or refraction.

You will never find a novice on any important task in any of our establishments. The average experience of the men in our service grinding departments is over seven years. Specialists they are in following the trade which can only be learned from years of hard, critical apprenticeship. To them accuracy is a rule never to be broken.

Just how well this rule works to the ultimate satisfaction of yourself and your patients can best be learned from the many Ophtalmologists who deal exclusively with us. The fact that the number of our satisfied customers is rapidly increasing, is ample proof that our work is better than those who claim theirs to be just as good.

And the speed with which we make delivery is an added feature of our service. Give us a trial, today.

STRICTLY WHOLESALE EVERYWHERE

Radium and Oncologic Institute

1052 West Sixth Street

LOS ANGELES

RADIUM THERAPY

An adequate quantity of radium and complete emanation apparatus affords the facilities essential for modern technique in radium therapy.

DEEP X-RAY THERAPY

Two complete 300,00-volt installations providing every facility for preliminary and post-operative Radiation and X-ray Therapy alone or in combination with other treatment.

X-RAY DIAGNOSTIC LABORATORIES

Completely equipped offer the profession every assistance for roentgenology as an aid in diagnosis.

HOSPITAL AFFILIATIONS

Including a complete high voltage X-ray and Radium Therapy department in the Methodist Hospital amply provide for cases requiring hospitalization.

LABORATORIES

Affiliated for clinical and pathological study and complete facilities for Actinic Ray Therapy.

This institution possesses unexcelled facilities for radium and radium emanation therapy and high voltage X-ray therapy. With modern X-ray diagnostic, clinical and pathological laboratories, complete equipment for electric coagulation, cautery and allied surgery, it offers the medical profession unexcelled facilities for the diagnosis and treatment of neoplastic diseases.

We desire to confer and co-operate with the Medical Profession in the treatment of cancer and other appropriate diseases and request inquiries either in person or by correspondence.

REX DUNCAN, M. D., Medical Director

What Does Treatment Based Upon a Wrong Diagnosis Mean?—"We knew of a patient," says the editor of Medical Review of Reviews, "with epilepsy who had been kept in fair condition for years. He was told finally that his epilepsy was caused by bones of his spine being out of place. Treatment on that basis brought about a series of violent attacks, rapidly repeated, in one of which the patient died. We knew of a patient with tuberculosis of the hip-joint. He was told that this condition was caused by bones of his spines being out of place. Because of a treatment on that basis, he developed an acute military tuberculosis and died. The patient probably was curable. We knew of a patient with a tumor of the breast. This patient was told that the tumor was caused by bones of the spine being out of place. The patient was informed that the tumor would disappear under treatment on that basis, combined with massage of the tumor. There was a rapid development of general carcinomatosis, and the patient died. This had probably been a curable case. We knew of a patient with dilatation of the heart who had been kept in fairly good health for years. He was told that this condition was caused by bones of his spine being out of place. On the basis of that diagnosis, treatment was given and he promptly died. We knew of a patient with chronic appendicitis following an acute attack. He was told the same thing about the bones of his spine. On the basis of that treatment combined with efforts of manipulative 'emptying of the appendix,' the patient developed an acute attack of appendicitis with peritonitis and died. This was a curable patient."

Every Rose Has Its Thorns—The declining death rates from tuberculosis and other preventable diseases imply that year after year more lives are transferred to middle and later life, there to be subjected to the increasing death rates from cancer and other causes characteristic of this age division of life.—Bulletin Metropolitan Life Insurance Company.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.
2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.
3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.
4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.
5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

SPECIAL ARTICLE

THE STATUS OF NEUROLOGICAL SURGERY— TODAY AND TOMORROW

By HOWARD C. NAFFZIGER, M. D., *San Francisco*

SURGERY of the nervous system, although one of the newer recognized specialties of medicine, already has made many valuable contributions to medicine, and has accumulated a large amount of literature.

Not every physician has the desire or the training to do neurological surgery, but there is much being done by special students of the subject of great value to all physicians.

It was with the object of bringing out the important developments in the specialty, and particularly the newer knowledge of value to all physicians, that Doctor Naffziger was invited to prepare this essay.—EDITOR.

NEUROLOGICAL surgery has emerged from its infancy to the age where it now makes more than a feeble outcry. Up to the time of the great war, it attracted the attention of but few surgeons. Since that time, and largely due to the experiences obtained in the war, an increasingly large number of well-trained men have devoted their attentions exclusively to it. In a considerable number of medical schools it has assumed its place as one of the major divisions of surgery. A large literature has grown up and a national society has been formed which is composed of men whose major interest is in this field. In this country particularly, the advances in this specialty during the past fifteen years have been remarkably great. These advances have been largely along physiological, diagnostic, and technical lines. It may be of interest to the physician who is not devoting particular attention to this field

to review some of the particular conditions and the considerations involved in diagnosis, treatment, and results. It seems safe to prophesy that the next decade will show remarkable advances in many of these lines.

INTRACRANIAL TUMORS

The physician, in thinking of the specialty of neurological surgery, is prone to think of brain tumors as being the particular condition most often seen. It is true that intracranial neoplasms represent the greatest problem in this field, and the most difficult conditions met. Of all organs, the brain, breast, and uterus rank together as common sites for tumors. In the whole range of cranial surgery, however, tumors represent only a part. Recognition of them occurs very much earlier than was the case a comparatively few years ago. During the past two years, at the University of California Hospital, not more than one or two patients have been received who were totally blind at the time of admission. This is a marked contrast to the numerous cases of total blindness common only a few years ago. It is not practicable here to go into a consideration of the various types of tumor pathology which are encountered. There is no pathological classification in general acceptance. It is sufficient here to consider intracranial tumors in two classes, the infiltrating growths, which are principally the gliomas, and the encapsulated growths. In the latter class one thinks particularly of the so-called dural endotheliomas (arachnoid fibroblastomata), the pituitary tumors and the tumors of the cerebellopontile angle. In a strict sense these are intracranial, but not cerebral.

GLIOMATA

The infiltrating growths are numerous, and the gliomas represent nearly one-half of the total number of the tumors. They constitute the most trying group, from the standpoint of both the patient and the surgeon. They are rapid in their progress and, being usually of the infiltrating type, are completely enucleable in only a few instances. Occasionally, radical resection can be performed. Under the gliomas may be included the gliomatous cysts and the cystic gliomas. The cystic change in gliomas is a favorable occurrence. It alters an apparently extremely serious outlook to one which is less grave, and is compatible with continued economic usefulness of the individual and a more or less indefinite span of life. It has not been long since the rather frequent cerebellar gliomas in children were considered a cause for deepest pessimism. A consideration of the results obtained in these cases, however, indicates that a considerable percentage of them, perhaps 20 per cent or thereabouts, pursue a favorable course after pressure effects are relieved at operation. In them the growth becomes entirely stationary, or so slightly progressive that

it seems stationary or a cystic change occurs. Freedom from symptoms over a three or five-year period is common.

PITUITARY TUMORS

The pituitary tumors are being recognized earlier, largely due to the interest and care of the ophthalmologist in carefully taking the fields of vision. Great strides have been made along technical lines in the handling of these conditions. Two main types of operative treatment have developed, namely, the transphenoidal route from below, and the superior route through a frontal or a temporo-parietal flap. The superior routes are, of course, the only ones practicable for the supra-sellar tumors, which are fairly common. In recent years there has been a considerable tendency for most neurological surgeons to favor this route also for the pituitary adenomata. It must be said, however, that there are but few operations in neurological surgery which give more satisfactory results than the transphenoidal operation in suitable cases. Those cases with more or less uniform enlargement of the sella and with no other neighborhood signs than defects in the fields of vision of one type or another are the ones usually selected. It is not unusual, however, for this operation to entirely relieve eye-muscle palsies which appear with the enlarging growth. These tumors are of slow development, and the relief obtained is immediate. Many of these cases have been followed post-operatively over a considerable number of years, without a return of any of their symptoms. One of the keenest pleasures is to witness the return of vision and the disappearance of hemianopsias. It is probably not generally appreciated that most individuals with pituitary tumors do not have acromegaly. The acromegalics are in a decided minority. The mortality from transphenoidal operations is low, certainly not more than 10 per cent,¹ and almost without exception post-operative convalescence is easy and rapid. The operative procedure itself places but very little tax on a weakened patient. All patients show the readily recognized signs of an enlarged sella turcica, as shown by the x-ray, and defects in the perimetric fields of vision which usually, at one stage or another, are of a bitemporal type. It is not uncommon, however, for homonymous hemianopsia to be found. The signs of disorder of the ductless glands, while usually present, are seldom the outstanding features of the case or the ones which bring the patient to the physician. Where the tumor has spread far above the diaphragm of the sella, as shown by marked effects on the third and sixth nerves or by pressure on one or another crus, operation by the superior route is necessary. This procedure, of course, permits of a more radical removal of the tumor, but is accompanied by an increased risk over the inferior route. It seems likely that with increasingly early recognition of the pituitary strumas, that the usefulness of the transphenoidal operation will be increased and the necessity for any other more formidable procedure thereby reduced.

ENDOTHELIOMAS

The dural endotheliomas or the arachnoid fibroblastomas, as they are more correctly termed, are among the most favorable types of intracranial tumor. It is not generally enough appreciated, and probably this is due to the unfortunate use of the term endothelioma, that these tumors are circumscribed, do not metastasize and do not recur after complete removal with a reasonable margin of the membranes from which they spring. Moreover, they are of slow growth, usually giving a history of years, and are most common over the vault and on the surface where they are accessible. The brain seems to stand slowly increasing pressure in an astonishing manner and even enormous growths, as one in our series, the size of an orange and weighing 220 grams, may be found without any manifestations of intracranial pressure, such as headaches or choked discs. Indeed they often cause so little disturbance that they may not be recognized until in some late stage they may so interfere with the cerebrospinal fluid pathways as to cause intracranial pressure. The late invasion of the overlying bones of the skull by these neoplasms and the recognition by the patient of a lump on his head as the first sign of tumor is well known.

TUMORS OF THE CEREBELLOPONTILE REGION

Of the tumors of the cerebellopontile angle, the acoustic tumors come first to mind, although this is not an uncommon location for endotheliomas as well as other types of new growth. In the recognition of acoustic tumors, their very slow growth is a characteristic feature and the chronological signs of tinnitus and deafness as the eighth nerve is increasingly involved, followed later by signs indicating pressure upon neighboring structures. Those most commonly involved are the fifth nerve with parasthesiae, numbness, and disorders of the sense of taste and of the seventh nerve with weakness or irritative signs. Pressure on the cerebellum is shown by faults in co-ordination on the same side of the body. In a large percentage of these patients some or all of these symptoms are present without the so-called classical signs of brain tumor, which are, of course, only signs of general rise in intracranial pressure, namely: headache, choked discs, and vomiting. By operation, relief from such pressure signs can be obtained. Complete removal of the growth can occasionally be accomplished. In the remaining ones, partial intracapsular enucleation is done.

Many of the tumors originating within the skull which are overlooked would be recognized, were one to always think of a tumor when they are dealing with any localized, but progressing lesion. Swelling of the optic discs as an indication of intracranial pressure from one cause or another, is widely appreciated. This one sign, whether it comes under the name of papillitis or choked disc, stands out as the most trustworthy and common sign of intracranial pressure. Sufficient experience with the ophthalmoscope to enable one to recognize this condition would save most of these cases from total blindness. Methods of localization of tumors as an aid to clinical neurology have received considerable attention.

DIAGNOSTIC AIDS IN LOCALIZATION

Pneumoventriculography, as introduced by Dandy, has received considerable attention, and is an unquestioned aid in the localization of tumors. It is a method, which, from the reports in the literature, involves a considerable degree of risk, but it is granted that the conditions for which it is done are ones which warrant taking such measures. Ventriculograms have been used in about eighty-five instances in this clinic. One fatality occurred after this procedure, but was due to a late hemorrhage. This procedure has added considerably to our diagnostic ability, but has not given a corresponding gain in the complete removal of tumors such as might be expected. The percentage of tumors which cannot be localized by methods of clinical examination alone has been variously estimated, and no accurate figures upon it are obtainable. It has been placed as high as 50 per cent (Dandy). It is probable that in 20 or 25 per cent an accurate localizing diagnosis cannot be made within a reasonable time without some other aid.

DISPLACEMENT OF THE PINEAL SHADOW

The following procedure, which has been developed in this clinic, is being published elsewhere. It has been of very real value and it involves no risks. In a large percentage of individuals, the pineal gland calcifies under normal conditions. In the lateral radiograms of the skull it is frequently seen. It is developmentally a true midline structure. When radiograms are properly taken in the anteroposterior position it can be determined whether this shadow lies exactly in the midsagittal plane or not. In cases with intracranial pressure, the shifting of the position of this gland can be utilized to great advantage. Any gross lesion associated with an increase in volume in the right cerebral hemisphere will cause this midline structure to shift, and the pineal shadow will be shown to the left of the midline. Likewise a shift to the right occurs with the gross lesion on the left side. When, however, there is a uniform rise of pressure within the skull due to a posterior fossa lesion or one at the base obstructing the cerebrospinal fluid pathways, there is an internal hydrocephalus. The dilatation of the two lateral ventricles is approximately symmetrical, and so in this instance the pineal retains its true midline position. Given an individual suffering from intracranial pressure, after the pineal gland is calcified, one is able to say whether he is dealing with a right cerebral or a left cerebral lesion or an internal hydrocephalus. This simple procedure greatly widens the diagnosis by x-ray and sufficiently localizes many of the otherwise unlocalizable lesions.

THE SPINAL CORD—DIAGNOSTIC AIDS

In the surgery of the spinal cord, several notable additions to our knowledge have occurred within recent years. It has not been so long since Sir Victor Horsley's first successful removal of a spinal cord tumor, in 1888.² Spinal cord tumors offer some of the most brilliant results seen in any field of surgery. Fortunately, most of these growths are benign. In the diagnosis of spinal cord compression in the absence of xanthochromia, Ayer's pro-

cedure of combined cistern and lumbar puncture has brought great certainty to our diagnosis. Combined puncture of the posterior cistern through the occipito-atlantoid region, if carefully performed, carries but very little risk, and with spinal puncture affords a ready index of the freedom of movement of the cerebrospinal fluid up and down the spinal canal. Alterations in pressure adjustments between these two levels, as shown by manometers attached to the two needles, gives striking evidence. Indeed, since, and because of the knowledge gained from the combined puncture, we are now in a position to obtain much more information from spinal puncture alone. It requires but little experience to note the rapidity with which changes in pressure occur in a manometer attached to a lumbar needle when the patient coughs or strains. Pressure upon the jugulars likewise shows a rapid change in the spinal pressure under normal conditions. Quantitative chemistry of the fluid obtained by cistern puncture, as contrasted with spinal puncture, gives added information. These diagnostic measures give reliable information as to whether there is or is not blockage of the spinal canal. For purposes of locating the level of the lesion, the use of lipiodol should be mentioned. This liquid, a combination of iodine in oil, is slightly heavier than cerebro-spinal fluid and upon introduction into the spinal canal, either by cistern or lumbar puncture, will gravitate to the level of the obstruction with the patient in the proper position, and the presence of the solution at this level will be shown by the x-ray shadow. It has been of value in giving accurate localization when a block is present. Its value is doubtful if no block can first be demonstrated.

CORDOTOMY

For the relief of intractable pain below the level of the upper extremities, cordotomy, or section of the anterolateral tracts of the spinal cord, as recommended by Spiller and Fraser, has come into use. While the applications for it are limited, it adds to our usefulness in certain most distressing conditions. In certain instances where the lease of life of the patient is manifestly short, it may be unwise to resort to a major operative procedure such as this.

ALCOHOL INJECTION

One will occasionally meet with such hopeless conditions as a complete paraplegia from metastatic malignancy to the spine, with terrific pain. When paraplegia is already complete, we have advised the injection of a small amount of absolute alcohol directly into the cord substance, by spinal puncture, just above the level of the lesion. The usefulness of such a procedure is, of course, very limited, but may serve an excellent purpose occasionally.

TIC DOULOUREUX

Certain neuralgias often demand the attention of the surgeon. Of these, the outstanding one, because of its frequency and severity, is tic douloureux. The diagnosis of this condition is usually simple. The pain most often first appears in the second or third divisions of the fifth nerve, later spreading to the first. Intermissions of months, or even years, are common. The characteristic pain is a terrific lanci-

nating, paroxysmal one of a few moments' duration which leaves the patient fearful and shaken, but entirely free from pain until the next one. There is rarely any continuous pain. Various types, which are comparatively infrequent, but which simulate true tic, have been described by Cushing. The group characterized by pain of this type plus marked contraction in the facial muscles of the same side is of most interest. These are not relieved by the measures which stop the pain in true tic. In true tic douloureux, alcohol injection of the second and third divisions of the nerve, and perhaps also of the supra-orbital branch, gives satisfactory, though temporary, relief and, in addition, confirms our diagnosis by showing that blocking of the nerve impulses will give relief. Neurectomies, when applicable, are of the same, but temporary value. It is, of course, a familiar experience to find that numerous other types of pain over the distribution of the fifth nerve area are not relieved by such a procedure. It seems worth while to emphasize the fact that operation, namely, section of the sensory root of the Gasserian ganglion, offers the only permanent relief in true tic douloureux. It does not seem to be widely known that properly conducted operations involve very slight risk, probably not more than 2 per cent. There are few of the major conditions in surgery in which relief is so necessary and in which the risk is so slight.

It seems unfortunate that there is not more familiarity with the clinical picture of this disease and the favorable results of treatment. The character of the pain is usually so distinctive that if it were more generally recognized much preliminary work would be saved. It is a rule for the patients to come after the extraction of all of their teeth and frequently with numerous operations upon the accessory sinuses, all of these things being done in a vain search for the cause of the trouble. There is likewise considerable misinformation as to the aftermath of the operation. The idea seems to be prevalent that facial paralysis and marked deformities are the rule. Facial paralysis is an infrequent complication and as far as we know is never permanent. The reason for its occurrence in occasional instances is not well understood.

OTHER FACIAL NEURALGIAS

Certain other types of facial pain seem to be associated with disturbances in the sympathetic system. Certain painful paresthesiae over the face are relieved by resection of the superior cervical sympathetic trunk.

Glossopharyngeal neuralgia, which is similar in character to tic douloureux, but in which the pain is referred largely to the throat in the region of the faucial pillars and to the ear is a condition less often encountered. It has been emphasized by certain of the French writers, and more recently by Doyle, Lillie, and Adson of the Mayo Clinic³ in this country. Its diagnosis can usually be made certain by the relief obtained by cocainizing the tonsillar fossa. Relief may be obtained by extracranial avulsion of the nerve or more permanent relief by intracranial section of it.

HYDROCEPHALUS

The treatment of hydrocephalus of infants or of the spinal deformities of infants associated with hydrocephalus still furnishes some of the most difficult problems. In certain types of hydrocephalus, the obstruction to the flow of cerebrospinal fluid may be localized and relieved. In a larger number the process is arrested.

HEAD INJURIES

In the treatment of head injuries, after reviewing the writings of surgeons early in the eighteenth century, and even before this time, one is inclined to feel that but little of value has been added to our knowledge of treatment. In the treatment of fractures of the skull with associated brain damage, the pendulum has swung from time to time from extreme conservatism to radical treatment, such as decompression for all, or nearly all. It seems to be the feeling of a considerable number of the conservative neurological surgeons today that the cases requiring operation are very decidedly in the minority. In the hands of those who are doing most of this work, the percentage of cases operated upon varies between 10 and 25 per cent. The basis of judgment for the cases needing operation is made not only upon the signs of pressure which are present, but upon whether or not they are progressing. The classical signs of acute intracranial pressure are well known. The most reliable ones are slow pulse, increased pulse pressure, and increasing stupor. These signs, however, are the ones presented by a normal brain which is reacting to pressure. The responses of a brain traumatized to various degrees and in various locations are bizarre. They do not always follow this clear-cut picture. It is in these cases that judgment is most difficult. These well-known signs, however, along with such aids as direct measurement of the spinal fluid pressure and observation of the eyegrounds in the more protracted cases, are helpful. In the acute traumatic cases, increased intracranial pressure is always due to an increased fluid content within the skull. This fluid may be present in the form of blood or an increase in cerebrospinal fluid, or through tissue edema resulting from the swelling of the contused brain. It is only by the removal of fluid that pressure can be relieved. The drainage of fluid by one route or another is the aim in any treatment. A decompressive operation which does not drain is usually ineffective. In addition to the removal of blood-clots and of subdural fluid accumulations⁴ by drainage through a small decompressive opening, there are other simpler methods which are of value. With large accumulations of free fluid, frequent spinal punctures are used. In true tissue edema, little or nothing is accomplished by such a procedure. The intravenous administration of hypertonic solutions of sodium chloride or Ringer's solution or the administration through the gastro-intestinal tract of magnesium sulphate, supplies other strings to the bow.

INJURY OF THE SPINAL CORD

Injuries of the spinal cord, with paraplegia or quadraplegia, are perhaps the most serious traumatic conditions with which one meets. There is the same

wide variation of opinion in regard to their treatment. Certainly, one can look back upon but few who have definitely been benefited by surgery. Injuries to the contents of the spinal canal below the level of the first lumbar vertebra are among the very favorable ones, and if taken in time much may be accomplished. All injuries of the cauda equina sufficient to give neurological findings below this level merit operative treatment. With the more common injuries just above this level, particularly those at the dorsolumbar junction, one is dealing often with a combined injury of the cord at the conus and an injury of obliquely placed fibers which go to make up the cauda equina. Often in these, little or nothing is accomplished with the cord injury. With the nerves going to the cauda equina, however, it may be possible to afford relief so that there is return of function through those which have their origin from a higher segment and yet are compressed at this point. A return of ability, even to flex the thighs, is of inestimable value to the individuals who are doomed to a hopeless paraplegia. It permits them to sit and even to carry on a certain amount of work. There seems to be no unanimity of opinion, or indeed any greater weight of opinion on one side or the other when comparing the advantages of operative against conservative treatment in injuries to the cord at a higher level. In the early stages it is usually impossible to differentiate between a complete physiological block and an anatomical interruption of the cord. Paralysis from continuing bone pressure is a popular idea with but little to support it. It is probable that the cord injury is an immediate destruction rather than one brought about by the continued pressure. Consequently, little can be expected in the way of operative relief. Compressions from blood clot are likewise unusual, and a suggestion of their presence can usually be obtained by spinal puncture. It frequently happens at operation, even in the presence of a complete paraplegia or quadraplegia, that the cord at the level of the injury appears normal to a casual examination. A small incision, however, into the dorsal columns of such a cord often shows that the entire gray matter is so pulped that it extrudes as a granular tan colored material. Injuries of the cord localized to a comparatively small area are sometimes seen. In these, the evacuation of devitalized material probably allows a greater degree of recovery. Even though most of the explorations are futile and discouragements are the rule, we feel that there are occasional, though rare, unquestioned benefits. A fair number of patients with cord injuries live for long periods. Existences under such conditions would no doubt make all of us wish that we had accepted any chance of benefit, however small. Lack of operative investigation in these patients usually becomes a life-long regret with them when complete paralysis persists.

BIRTH INJURIES

The birth injuries which have resulted in Little's disease or the cerebral spastics of one type or another, are a constant problem. In a few of them early operations are of enormous benefit. In the older children these conditions, many of them hope-

less, have been a fertile field for exploitations. Rarely at a late stage can they be benefited by any cerebral operation. Their lesions are destructive and developmental ones. In occasional instances where the process is well localized and where the spasticity has been increasing, or convulsive attacks have appeared, operative intervention may be advisable. Of work, that which has created the most interest is that of Drs. Royle and Hunter of Australia.⁵ It seems as yet too early to offer an opinion as to the final status of the procedures which are adopted by Royle, namely, sympathetic ramisection. The cases adaptable to this procedure are limited in number. It is not invariably easy to select them wisely. The operation can be applied only to those in whom a considerable degree of voluntary power is present. Royle's operation has provoked much comment, both favorable and unfavorable. There can be no doubt, however, but that certain very definite results are noted and that in certain of the cases, the procedure has been a decided advantage. It is an operation which permits such voluntary power as is present to be used, but it does not restore voluntary power.

PERIPHERAL NERVES

The surgery of peripheral nerves probably received more of an accretion to our knowledge from the experiences in the great war than any other phase of the surgery of the nervous system. It brought general appreciation of the fact that end-to-end suture of the nerves, without the aid of extraneous substances, was not only the ideal procedure, but was really the only worthwhile one. Autografts or homografts, while they are of great experimental interest and do permit of regeneration through them, do not add sufficiently to the functional improvement to make them worth while. The importance of early exploration and early nerve suture in doubtful cases was one of the most useful lessons. The long waits to determine whether or not regeneration is occurring have been disastrous and have removed the last chance for the patient to gain anything like a satisfactory result. It is probably not so much that regeneration will not occur when suture is performed late, but that the motor apparatus will no longer be in condition and cannot be kept in condition to receive it. While the importance of physiotherapy to prevent stiffening of joints and proper splinting to prevent overstretching of the muscles were of great value, it became obvious, on the other hand, that the time-honored electrical treatments and massage of muscle bellies did nothing to either hasten recovery or augment it. The experimental research of McLeod and his co-workers at Toronto entirely explodes the idea so long held of the usefulness of faradic and galvanic treatment of the paralyzed muscles.

The scope of neurological surgery permits that mention only can be made of these varied conditions.

Steady advancement on the amelioration or cure of numerous other conditions can but be mentioned. The difficulties in the treatment of brain abscess and how to meet them have received a great share of attention, the amelioration and cure of certain cases of meningitis have all been advances in the handling of acute infections of the central nervous system.

Peripheral nerve surgery in civil life has received attention in the lessening of certain forms of spasticities, in nerve sutures for facial palsy and for palsy of the recurrent laryngeal nerve.

Cervical operations upon the phrenic for intractable hiccup and for immobilization of the diaphragm in pulmonary tuberculosis are receiving consideration.

Resection of the various portions of the cervical sympathetic system or the pain in angina pectoris has been followed in numerous instances by striking relief. It is easily performed under local anesthesia. We have seen patients return to work after long periods of distress and incapacity. It is recognized that such a procedure can have no curative effect on the underlying pathology. Notwithstanding this, the measure of relief has been great enough so that the patients consider it highly satisfactory.

EPILEPSY

Mention should be made of the epilepsies. Certain of the focal epilepsies have a surgical lesion as their basis, and demand surgical attention. In the more common general convulsive states, the convulsions are but a single manifestation of a widespread brain affection. The immediate basis for the convulsions, whether it be circulatory, chemical or from some other cause, is as yet unknown. In such conditions the extreme plight of the patient supplies a field for the overenthusiastic operator. Some epileptics are said to have remained free from convulsions after having had their skulls fractured. Such operators may act only in the role of the traumatizing agents. In the present state of knowledge of the subject, our energies can best be directed toward a solution of the problem rather than to misguided surgical attempts to cure convulsions.

The range of neurological surgery has so widened, and the impetus in its advancement is so great, that the next decade should show many brilliant accomplishments.

The requirements in diagnosis, the character of preparation for such work and the technical procedures themselves are such as to merit specialization in this field. Men interested in it may question the advisability of selecting it on the score that it is too limited. Probably this has always seemed true in contemplating limitation to any specialty. The greater the number of well-trained individuals interested in the same problems, the greater will be the amount of work and the progress in it.

SURGICAL TREATMENT OF DISEASES OF THE COLON

By C. E. PHILLIPS, M. D., Los Angeles, Calif.

I believe we can say that the cecostomy performed in the manner outlined furnishes us one of the best possible means of treatment of many of the severe pathologic conditions of the large intestine, sigmoid and rectum, because it allows us to treat them on the sound surgical principles of rest and cleanliness.

DISCUSSION by A. B. Cooke, Los Angeles; Emmet Rixford, San Francisco; George K. Knapp, St. Helena Sanitarium; Frank H. Paterson, Santa Ana; M. S. Woolf, San Francisco; Rea Smith, Los Angeles.

THE colon is an organ for absorption and a receptacle for waste. This dual function requires it to be resistant to the most virulent catabolic poisons and at the same time allow the products of digestion to pass readily. The limiting wall which stands between the living organism on one hand and substances capable of destroying it on the other, is the mucosa. In a state of health it permits the passage of water and nourishment, but obstructs the passage of the common substances deleterious to the organism. Certain accidents of nature occur which alter or destroy this function, and a diseased condition results. We may say, roughly, the severity of the disease depends on the disproportion existing between the pathologic factor on one hand, and the tissue resistance on the other.

The etiology of diseases of the colon can be divided into two general classes: predisposing and exciting. Certain conditions arise which predispose to colonic diseases. Many of these bring it about in a twofold way: (1) By lowering the resistance, and (2) by increasing the virulence of the attacking organism.

Probably the first predisposing factor that should be mentioned is stasis. The second is toxins arising from improper food, faulty digestion or decomposition. The third is systemic diseases interfering with the normal process of absorption and elimination. The fourth, anatomic anomalies, malformations, and distortions.

The exciting causes we may classify in order of their importance: First, bacterial and protozoic infections of the colon. Second, animal parasites. Third, catabolic poisons. Fourth, inflammations and new growths extending from adjacent structures.

PATHOLOGY

(It is not the author's intention to take up the subject of pathology of colitis except in a very general way.)

Pathologic conditions of the colon may attain any degree of severity, from a simple inflammatory condition which will recover spontaneously to a fulminating process leading to extensive destruction. When the latter takes place the faculty of tissue repair is lowered. Healing takes place, if at all, with the formation of scar tissue. First, this causes deformities by contraction and interferes with the normal function of the bowel. Second, the scar tissue does not possess the non-abrasive or the non-corrosive faculty of the normal membrane.

The result is that extensive ulceration heals with great difficulty, and when healing does take place

Figure 1.—Shows diagrammatically the position of the ileocecal valve, the caput coli, the appendix, and the part of the cecum (c-b) which is to be stitched to the abdominal wall at (a-d).

recurrences of ulceration are common. Lesions of the bowel may assume almost any form. Perforation from infection is very rare. We can roughly state the greater the destruction the more serious the condition. Hence, our effort should be to prevent extensive damage rather than repair extensive lesions after they have formed.

DIAGNOSIS

To determine the cause of the trouble is not sufficient. We must also ascertain the severity, progress, duration, and extent, before we can intelligently decide upon the treatment to be employed. There are certain aids in diagnosis which must not be overlooked. A careful physical examination, noting the systemic effects of the infection or growths; the x-ray; the proctoscope or sigmoidoscope; the laboratory examination of the excreta and serological tests, are the usual. In some patients an exploratory incision is advisable. From whatever cause the disease arises, a careful and exhaustive study should be made. An early and complete diagnosis must be made if the patient is to receive the maximum benefit from the type of treatment selected.

PROGNOSIS

Prognosis will depend upon: First, condition at institution of treatment. Second, the kind of treatment employed. No line of treatment will restore a colon whose mucosa has been extensively destroyed and from which destruction cicatrices and deformities have resulted. Even the most malignant infection, if treated early by the application of physiologic rest and surgical cleanliness, may be cured without sequellae. We should no more temporize with a destructive lesion of the colon than with a similar condition of the appendix or gall-bladder. While the immediate dangers are not so great in the former, yet if a large number were carefully

analyzed, the average morbidity in the severe colitis cases would exceed that of a like number in appendicitis or cholecystitis.

TREATMENT

The difficulty of treating diseases of the colon is apparent. The multiplicity of remedies implies their inefficiency. The two prime essentials for the treatment of infection anywhere are rest and cleanliness. The two prime essentials for treatment of colonic diseases are the same. The difficulty in attaining these conditions renders their application inadvisable except in those cases where failure to employ them may lead to disaster.

By medication and irrigation, direct treatment to the colon is carried out and drugs produce relative rest. Yet the impossibility of relative cleanliness without sidetracking the bowel is evident to all. Without freeing the bowel of irritating contents, rest is not always desirable. The urgency of treatment that will arrest disease process before irreparable injury has been done, is likewise self-evident. Under no circumstances should a patient be taken to surgery when satisfactory healing will take place by simpler means. On the other hand, a patient should not be permitted to reach a state where irreparable damage has been done without recourse to this means.

Let us lay down some general rules where surgery is indicated: (a) *Acute infections* of the colon which have not responded to the usual line of medical treatment and where the continuance of the disease threatens the life of the patient. (b) *Chronic infections* of the colon which have not responded to the usual treatment and which are so severe that a continuance may lead to stricture, malignancy or a serious interference with the general health. (c) *In neoplasms* of the intestine, where it is essential to prevent irritation by diverting the intestinal contents. (d) Where operative work on the large bowel is contemplated, a sidetrack is frequently desirable.

In contemplating an operation of this kind, we must take into consideration certain factors: The first is danger: The operation I shall describe is simple, can be done in case of necessity with a local anesthetic, requires but little time in its performance, and per se should have practically no mortality rate. The second is disability: While the patient with a cecostomy is not confined to bed, to the house, or prevented from attending to light business, yet its employment is sufficiently unpleasant to contra-indicate its use except under certain conditions. The third is nutrition: Nutrition is not seriously affected by sidetracking the entire large bowel. With a careful regulation of diet there is comparatively little inconvenience and even a rapid gain in weight may take place. The fourth is repair: A restoration of the continuity of the bowel is effected with ease when healing has taken place.

OPERATION

The site of operation is in the right iliac region. The object is the temporary sidetracking of the entire lower bowel. An incision is made through the skin as in the McBurney incision for appendectomy. The muscle fibers of the external oblique must be

Figure 2.—Shows the selected portion of the caput coli and appendix, presenting through the abdominal wound: the ascending colon is fixed to the abdominal wall by a stitch to prevent a prolapse of the ascending colon and thus interfering with the protrusion of the ileocecal valve. The presenting portion of the cecum is grasped by forceps and the distal portion is to be excised.

more than separated. They must be cut obliquely so that a stricture will not form about the intestine when the partial prolapse occurs. The fibers of the internal oblique and transversalis are cut transversely, or, in other words, the oblique incision is carried through all the layers of the abdomen and extends for a distance of about two and one-half inches. The head of the cecum is brought up, and the portion selected for the opening is just opposite the ileocecal valve, starting about one-half inch from it and continuing around the end of the cecum for a distance of about two inches (Fig. 1). This portion of the cecum includes the appendix and longitudinal band extending to the appendix from the ileocecal valve. The parietal peritoneum is stitched to the visceral peritoneum allowing a fold of the cecum about two and one-half inches longitudinally and one and one-half inches vertically to show, including the appendix. This suture approximates the parietal and visceral layers of the peritoneum. It is put in carefully and must prevent leakage. Before the peritoneum is closed completely, another stitch is applied at the upper angle of the incision fixing the longitudinal band to the parietal peritoneum above the incision (Fig. 3), so that when the partial prolapse of the bowel occurs, the ilio-cecal valve will evert rather than the proximal part of the cecum. The closure of the peritoneum is then completed. The exposed part of the bowel (two inches in length and including the base of the appendix and wide enough to include the entire thickness of the intestinal wall), is grasped with a clamp (Fig. 2). A few stitches are taken to approximate the muscles and fascia to the bowel proximal to the bite of the clamp. Two or three mattress sutures are inserted through the skin and muscular layers approximating them to the cecum. The constricted portion is excised distal to

the clamp, so that when the clamp is removed the bowel opens. The wound is covered with petrolatum, and a dressing is applied over the clamp. On the following day the clamp is removed. The bowel opens immediately. Fluffed gauze dressings changed frequently take care of the discharge. There follows a slight prolapse of the ileocecal valve through the opening (Fig. 3). Stitching the cecum to the parietal peritoneum above brings the ileocecal valve through the opening, and we have a complete side-tracking of the entire large bowel. This prolapse of the ileocecal valve remains and thus cuts off entirely the fecal matter passing through the large bowel. The prolapse never exceeds the distance of an inch or so because the mass of the cecum is too great to extrude out of the rather small muscular opening. The small size and sphincter-like action of the opening likewise prevents a continuous discharge from the ileum. By a proper regulation of the diet, restriction to foods with small residue, and by taking liquids in small amounts at frequent intervals, bowel evacuations are limited to two or three a day. Irrigations and treatments to the large bowel can be carried on by flushing either from above or below. Flushing from below and having the flow come out the cecostomy opening lessens peristaltic action, thereby affording more complete rest. After trying various medicinal irrigations, we come to the conclusion that rest is by far the most important agent in practically all conditions requiring the operation. In the acute cases, continuous irrigations through the rectum will tide over many who would otherwise succumb to toxemia. Ulcerative conditions will heal most readily with rest and an occasional mechanical cleansing by flushing with plain water. With the patient relatively comfortable, a colostomy bag is applied which permits getting about in a fairly normal manner. The cecostomy is allowed to remain functioning until complete recovery or maximum improvement of the bowel has taken place. When we are satisfied, after careful examination, that healing is complete or maximum improvement has taken place, the continuity of the bowel is re-established.

CLOSURE

Anesthesia—A general or regional, but not local, should be employed. A careful cleansing of the colostomy opening, and of the skin about it, should be first performed. An incision is then made around the prolapsed bowel in the muco-cutaneous junction. The mucosa is liberated just sufficiently to permit suturing the edges with the mucosa inverted. This suture is continuous and put in with sufficient care to insure a tight closure. The suture material is some kind of antiseptic catgut. When the closure is complete the entire wound is thoroughly iodized, and then a debridement is performed by dissecting off all the iodine-stained tissue. Whatever infectious material was in the wound is thus fixed by the iodine, and its removal is insured by the excision. Following this the cecum is freed and the peritoneum opened. The cecum is closed by a second layer of sutures which further folds it in until normal peritoneum only is presenting. The restored cecum is

Figure 3. — Shows diagrammatically the ileocecal valve prolapsed and enlarged through the abdominal wall. The opening into the large intestine is just above the ileocecal valve.

dropped back into its normal habitat and the abdominal wall is closed by layer suture.

In conclusion, I believe we can say that the cecostomy performed in the manner I have outlined furnishes us one of the best possible means of treatment of many of the severe pathologic conditions of the large intestine, sigmoid, and rectum, because it allows us to treat them on the sound surgical principles of rest and cleanliness.

523 West Sixth Street.

DISCUSSION

A. B. COOKE, M. D. (Hollingsworth Building, Los Angeles)—Doctor Phillips' admirable paper directs our attention to an important and much-neglected subject. We are prone to regard affections of the colon as medical maladies, treating them as such oftentimes until damage has been done which even surgery cannot undo. It is undoubtedly true that early resort to the operative treatment described, in properly selected cases, would reduce both morbidity and mortality.

The technique of cecostomy as outlined by the essayist is clear and possesses the virtues of simplicity and efficiency. A feature of the utmost value is that it permits the ready restoration of the bowel continuity when the therapeutic purpose has been served.

I should like to mention the application of this operation in cases of intestinal obstruction. It is always desirable to relieve the obstruction in acute obstructive conditions by opening the gut as far proximal to the site of stenosis as possible, in order that subsequent more radical surgery may be performed in a relatively clean field. Cecostomy offers this advantage whether the causative lesion be located in ascending, transverse, or pelvic colon. I think this is an important point to bear in mind.

EMMET RIXFORD, M. D. (1795 California Street, San Francisco)—The technique described by Doctor Phillips for cecostomy is ingenious and would appear to have distinct advantages over the operation as ordinarily performed, particularly because, by virtue of prolapse of the ileocecal valve, practically complete drainage of the intestinal contents can be effected.

It is a question whether cecostomy will altogether supplant appendicostomy where it is desired to maintain an opening in the cecum for a long time for irrigating purposes. As a preliminary operation preparatory to removal

of the rectum for carcinoma or syphilitic stricture, I believe left inguinal colostomy is preferable in most cases because of the preservation of the colonic function of absorption of fluids, but it must be done with due regard to the amount of the lower bowel which it is proposed to remove.

GEORGE KNAPP ABBOTT, M. D. (St. Helena Sanitarium, Calif.)—Those surgeons who have given to surgical science the most lasting contributions have built their methods upon a careful study of normal and pathologic physiology. Nevertheless, experience is such a valuable teacher that one hesitates to express any decided opinion regarding new procedures.

Severe colitis, without ulceration, is so intimately bound up with pathology of other parts, or even with so-called nerve exhaustion, as to render it more largely a symptom or an accompaniment of other disease than a disease *sui generis*. Its cure is usually a matter of the removal of disturbing nervous factors or reflex nerve irritation originating in pathology of the appendix, pelvic adnexa, gall-bladder, focal infection, etc. The field for cecostomy would seem to be largely in ulcerative colitis that resists ordinary non-surgical measures. The importance of complete physiologic rest in the treatment of ulceration of hollow viscera has been well demonstrated in the surgical experience with duodenal ulcer. The success of gastroenterostomy depends upon the completeness with which the food current is diverted through the new opening. Severe or extensive ulcerative colitis yield to cecostomy and appendicostomy. Dr. Phillips' careful technic should give the former a recognized place in physiologic surgery.

FRANK H. PATERSON, M. D. (Walter L. Moore Building, Santa Ana, Calif.)—The value of cecostomy in the presence of such pathologic conditions of the colon as mentioned by Doctor Phillips has been gaining ever-increasing recognition since the work of Weir in 1902, preceded by a decade by the observations of Councilman and Lafleur and the subsequent work of Musgrave and Clegg.

The manifest benefits of this operation (and also appendicostomy) over all other forms of therapy in those intractable amebic infections so frequent among our veterans of the Spanish-American War who had seen service in the Philippines, gave distinct impetus to its employment in other forms of colon disease.

The technic devised by Phillips appears to possess advantages in the consequent position of the ileocecal valve which serves to cut off entirely the passing of fecal matter through the large bowel, thus enhancing the degree of rest to the latter structure which the operation was principally designed to accomplish. A further factor in its favor is that it does not preclude the possibility of irrigating the lower segment of the bowel either from above or below, should this be indicated. The ease of restoration of the gut to approximate its previous anatomic relations constitutes a third favorable element.

A review of a series of appropriately selected cases in which this technic had been utilized should prove a matter of considerable clinical importance.

M. S. WOOLF, M. D. (240 Stockton Street, San Francisco)—The procedure of Doctor Phillips for resting and cleansing the large bowel in certain types of colitis should prove a valuable contribution in treatment of this disease. I see many advantages in unloading the ileum by an opening which is large enough to evacuate everything and yet does not permit fecal contents to pass over the ulcerated surfaces. If cecostomy can be done, it will mean that the ileum is not affected and that the cecum itself is not diseased. There are, however, some patients in which both cecum and lower part of the ileum are the seat of ulcers. Before reading Phillips' paper, I was rather inclined to favor an ileostomy to divert the fecal current, but I see no reason why a cecostomy, with a prolapsing ileo-cecal valve, might not do everything that an ileostomy does, if the cecostomy does not involve a dangerous area. In addition, since the appendix may be made to protrude through the same opening as the cecum, one might give appendicostomy a trial before even entering the cecum. Lockhart Mummery favors an appendicostomy in these cases. Since Doctor Phillips read his paper, I have wished to perform his type of operation, but the only case that has come into my hands since that time had such evident signs of in-

flammation about the appendix and cecum that I was obliged to open the ileum.

REA SMITH, M. D. (1136 West Sixth Street, Los Angeles)—The technic of cecostomy as described by Doctor Phillips interests me very much. I have occasionally done a cecostomy in the ordinary way, usually in a hurry to relieve a complete obstruction lower in the colon, to be followed by a secondary operation. Cecostomy has proven a great benefit at the time of the secondary operation in keeping the gas pressure off the stitch-line, but it has been closed with difficulty.

It seems to me that the operation as described by Phillips can be done just as quickly as the ordinary procedure of stitching the cecum into the wound at its presenting point, and it gives a very much better intestinal drainage at the time it is needed, and is more easily closed afterwards. As a means of sidetracking the colon to provide rest in the treatment of ulcerative colitis, it is certainly a more positive procedure than appendicostomy or simple cecostomy, and I shall use it at my first opportunity.

DOCTOR PHILLIPS (closing)—I want to thank the men who have so ably discussed my paper. The operation is not offered as a cure-all for all gastro-intestinal ailments. The indications for its employment are clearly defined. My hope is that the procedure will be given a fair trial in cases where rest, drainage and disinfection of the colon are indicated. I am sure the procedure will be found as satisfactory in the hands of others as it had been in my own.

Simple cecostomy has been employed in certain diseased conditions of the colon for a long time, and it was in performing this operation that I found that some cases automatically sidetracked the large intestine, while in others only a fistulous opening resulted. In an attempt to analyze the results, the present procedure was devised and has proven very satisfactory in a large number of cases.

Morphin: Before and After Operations—A questionnaire sent out by M. A. Slocum, Pittsburgh (Journal A. M. A.), on the use of morphin before and after operations leads to the following conclusions: The surgical profession is distinctly not in accord regarding the use of morphin before and after operations. The reasons given, by surgeons in general, for not using morphin differ widely. It is a curious fact that one group of prominent men condemns morphin as definitely producing unfavorable symptoms, while another group advocates its use because it prevents these very symptoms. This questionnaire clearly establishes the fact that a majority of surgeons are in favor of morphin pre-operatively and post-operatively in practically all cases. At the present time there is less fear of using morphin in surgery than there was twenty years ago. Whether this should be a danger signal or whether it has come about because of advances in knowledge remains to be proved. An attempt should be made to set some sort of standard by which we can be guided in our use of morphin. While it is admitted that it is difficult to standardize the use of drugs in general, it is felt that morphin is of sufficient importance, and in general enough use in surgery, to merit at least a trial toward standardization. There seems to exist a vast field for research, animal and otherwise, in the therapeutics of morphin. It is true that there is a great deal known about the pharmacology of morphin. However, there is little mention in the literature of work done on animals regarding the effects of morphin on the kidneys, circulation, gastro-intestinal tract and respirations.

Needs More Study—Honey is said to contain all the essentials for animal life. The average quantity of water is 17.2 per cent; mineral salts, 0.75 per cent, and protein derived from pollen of plants, 1.8 per cent. The proportion of grape sugar and fruit sugar to the other solid constituents is ten to one. Honey contains 1.1 per cent formic acid and 0.3 per cent of mallic acid and 0.2 per cent of acetic acid. It is possible that honey contains all the vitamins necessary for life; it is the sole food of the bee.—Lancet.

TREATMENT OF CHOLECYSTITIS

By W. W. BOARDMAN, M. D., San Francisco
(From the Gastro-Intestinal Clinic, Stanford University Medical School)

No rule of thumb methods.

It is not primarily a question of medical as opposed to surgical methods.

Many factors, sociological and medical, have a bearing on the choice of treatment.

DISCUSSION by Walter C. Alvarez, San Francisco; Wade H. Walker, Long Beach; L. G. Visscher, Los Angeles; Charles D. Lockwood, Pasadena.

NO procedure as yet devised has given uniformly satisfactory results in the treatment of cholecystitis. As our knowledge of the physiology and pathology of the hepato-biliary system increases, we may anticipate the development of more rational and more successful prophylactic and therapeutic measures, but at present this knowledge is far from complete, and our efforts are, therefore, more or less empirical and unsatisfactory. In order that we may have as clear a conception as possible of our therapeutic problem, it will be well to briefly review some of the more recent additions to our knowledge in this field. First it is essential to bear in mind that the gall-bladder is not an isolated and independent organ, but that it is an integral part of the hepato-biliary system, and that factors influencing one part of the system may, and usually do, influence the remaining parts.

There has been much discussion regarding the function of the gall-bladder, but the work of Mann, Rous, MacMaster, and others has demonstrated that it is not essential to life, that it acts primarily to concentrate and store bile in the interdigestive periods, that it apparently acts to decrease the alkalinity of its contents, that it probably acts as a safety valve in the biliary system allowing rapid equalization of pressures, and that it has a mucous secretion.

It is this ability of the gall-bladder to concentrate the bile rapidly and to about one-tenth of its original volume that enables it, with a normal capacity of 50 cc., to store the large amounts of bile secreted in the interdigestive periods. The secretion of bile is continuous, and varies from 500 to 1500 cc. per day, but the excretion of bile into the duodenum is intermittent, occurring normally only during the digestive periods.

The excretion of bile is controlled by the sphincter of Oddi, which relaxes in response to the stimuli produced by digestive products in the duodenum. The resulting discharge of gall-bladder bile is apparently partially due to an active contraction of the gall-bladder as suggested by Meltzer, and partially to a passive emptying in response to the fall in pressure in the common duct. This emptying of the gall-bladder is always incomplete, so that even under normal conditions there is some gall-bladder stasis which may be greatly increased by various abnormal conditions.

Liver bile is alkaline in reaction, but the recent work of Drury shows that in dogs, rabbits, and from a limited number of observations in man also, the gall-bladder bile is acid-neutral, or very weakly alkaline. This decrease in alkalinity, which seems to be produced by the gall-bladder itself is, from Drury's work, of the utmost importance in preventing the precipitation of cholesterol, calcium carbo-

nate and calcium bilirubinate from a concentrated and static gall-bladder bile.

The secretion and composition of bile is largely dependent upon the composition of the portal blood which brings to the liver cells the products of absorption from the spleen, the stomach, the small intestine, and the proximal half of the large intestine. Bile contains four important groups of substances; the bile pigments, the bile salts, fatty materials, especially cholesterol, and the inorganic salts, especially calcium. The bile pigments are the products of hemoglobin catabolism; the bile salts are of obscure origin; cholesterol is apparently partly derived from certain body tissues and partly from certain foods, especially yolk of eggs, butter, cream, and animal fats. Under certain normal and abnormal conditions, the quantity of one or other of these bile constituents may be increased with a resulting increased tendency for precipitation to occur. As already stated, such precipitation seems normally to be prevented by the decreased alkalinity of the gall-bladder bile.

Infection of the gall-bladder is essentially an infection of the deeper layers of the wall, and not an infection of the mucosa or of the contained bile. The question of the mode of infection of the gall-bladder remains unsettled. Five possible routes have been suggested: 1. Ascending infection from the duodenum. 2. Descending infection from the liver by bacteria carried out in the bile. 3. Hematogenous infection. 4. Spreading infection by chance contact with some inflamed organ. 5. Lymphatic infection from a previously infected liver. The experimental and clinical evidence seems to indicate that the ascending and descending infections are infrequent in previously normal gall-bladders, but may be of considerable importance under abnormal conditions such as occur with stasis from obstruction, stones, or serious injury to the wall of the gall-bladder. The hematogenous route, as especially emphasized by Rosenow, has gained wide acceptance, and is of undoubted importance. Infection by chance contact with inflamed organs is of infrequent occurrence.

Graham and Peterman have recently advocated the lymphatic route from a previously infected liver. They call attention to the intimate lymphatic connection between the right lobe of the liver and the gall-bladder, and have demonstrated the presence of hepatitis in practically all cases of cholecystitis. This latter finding has been confirmed by Judd and others. From their experimental and clinical investigations, they conclude that: "In many cases, probably in a majority, cholecystitis represents a direct extension to the wall of the gall-bladder from a liver already inflamed. The hepatitis usually begins and is most marked in the interlobular or periportal tissues, and it is apparently due to infection brought to the liver by the portal vein, and more rarely perhaps by the hepatic artery. Pericholangitis then occurs, and because of the intimate anastomosis between the lymphatics of the intra-hepatic and extra-hepatic biliary systems, direct extension into the wall of the gall-bladder takes place as well as into the common duct and the pancreas. From the hepatitis, therefore, a cholecystitis, choledochitis, and pancreatitis can be understood to occur, if in the consideration of inflammations in this locality we apply

the well-known fact concerning inflammation in general, namely, that it extends by way of the lymphatics. We believe that the ideas expressed in this article explain more readily than any others heretofore offered the frequent and well-recognized association of biliary tract infections with lesions of the portal system (appendicitis, peptic ulcer, typhoid fever, suppurating hemorrhoids, etc.)."

After reviewing the evidence in favor of the various possibilities, it seems apparent that, in the study of the etiology of the individual case, each route must be given due consideration.

Finally, regarding the question of stone formation, we are almost totally lacking definite knowledge. It has been accepted that infection, stagnation of bile and increased concentration of one or more of the bile constituents, especially cholesterol, were apt to lead to stone formation. Of these, infection has been considered of prime importance, although it has been maintained that the single pure cholesterol stone might be formed in the absence of infection. Practically all stones form about a central nucleus believed to consist primarily of organic debris, usually of inflammatory origin, such as the various sediments present in pathological gall-bladders, clumps of bacteria, etc. However, practically none of these ideas have been subjected to experimental proof, and a careful analysis discloses many uncertainties. The recent work of Rous, Drury, and MacMaster seems to promise more definite information. They have demonstrated the possibility of stone formation in dogs in the absence of "influences to which many authors have accorded primary significance, namely, infection, stasis, and gall-bladder activity."

They observed the development of two types of stone: one, the calcium carbonate stone which was found to form only within and not upon the surface of organic debris which had been retained for some time, and apparently undergone changes favoring carbonate deposit, and they question "whether the active inflammation found in association with human carbonate stones may not tend to their formation by providing in inorganic debris a chemical nidus for deposition, while so interfering with the ducts that this debris is not voided as it would be under more ordinary conditions, but retained to undergo changes preliminary to carbonate deposition." The second was the mixed type, especially those containing much bilirubinate which form about special centers of deposition. These centers were formed from the abnormal bile secreted after liver injury of various types, and were composed of calcium carbonate and calcium bilirubinate, together with an organic scaffolding. In human bile in the absence of infection, they have found similar nuclei composed of calcium carbonate which in their impression are derived from the contents of abnormal gall-bladders and which undoubtedly act as centers of deposition.

Finally, they call attention to the fact that, although liver bile is quite definitely alkaline, gall-bladder bile in the dog, rabbit, and apparently in man, is less alkaline, neutral or acid in reaction. This change in reaction appears to be brought about by the activity of the wall of the gall-bladder and independent of its concentrating function. The importance of this finding lies in the fact that calcium

carbonate, cholesterol, and presumably bilirubinate, will precipitate from alkaline solutions, but not from acid. In other words, it seems probable that the development of the nuclei above noted and the growth of stones in the human gall-bladder may be dependent upon a failure of the gall-bladder, through one cause or another, to alter the reaction of its contents.

From this brief review, it is evident that much uncertainty exists regarding essential questions of etiological importance in the development and persistence of cholecystitis, but from it we may build up a working hypothesis to guide us in our therapeutic efforts. Thus, in cholecystitis we are dealing with an infection not only of the wall of the gall-bladder, but of the liver, the bile ducts, and the pancreas. The primary infection may have been an acute generalized infection, or a focal infection drained by the portal or systemic circulations. Infection once established may so alter the composition and reaction of the bile and the motility of the biliary system that conditions essential to stone formation are produced. Stones once formed, either secondary to infection, to metabolic disturbance, or to alterations in the reaction of the gall-bladder bile, favor the persistence of existing infection or the occurrence of secondary infection.

From this it follows that for the prevention of cholecystitis we must first seek and remove foci of infection at the earliest possible moment, rather than to await the development of complications.

Secondly, we must recognize the existence of periods of special danger such as occur during the later months of pregnancy; during and after the acute infections, especially typhoid; during and after inflammatory process of the large or small bowel. At these times we must try to overcome any tendency to biliary stasis; overconcentration of any of the bile constituents, especially cholesterol; any normal or toxic overstimulation of the liver by poorly balanced diets, overfeeding, irritating types of food and drink, and irregular bowel action, and finally by general hygienic measures, especially mental and physical rest, to as quickly as possible restore individual resistance.

Therapeutically, our indications are: 1. To recognize the inaugural symptoms of cholecystitis and to institute proper treatment before such extensive organic changes have occurred that the restoration of functional efficiency is rendered doubtful or impossible. 2. To prevent further infection of the hepato-biliary zone from primary areas of infection, either in the portal or systemic areas. 3. To prevent, as far as possible, the occurrence of liver injury by materials absorbed from the gastro-intestinal tract or elsewhere. 4. To prevent or correct metabolic disturbances which result in increased concentration of one or more of the bile components. 5. To eliminate the existing infection in the gall-bladder, liver and ducts. 6. To remove any mechanical irritation or obstruction in the biliary system. 7. And, finally, to build up the general body resistance.

How may these various objects be attained?

First, and of prime importance, is the crying need of earlier diagnosis. We must not allow our patients to go on for from five to twenty-five years

with diagnoses of "nervous indigestion," "flatulence," "dyspepsia," "biliousness," "auto-intoxication," "neurasthenia," and a host of other such meaningless terms and with equally aimless and random treatment, while the pathological processes are slowly progressing to such a point that at length we are forced to a realization of the true condition. Only too frequently this realization awaits the onset of some dramatic and often tragic surgical complication or the development of marked degenerative changes in other organs. There seems to be a natural hesitancy on the part of the profession to diagnose cholecystitis until forced to do so, and yet when we recall the frequency of its occurrence this hesitancy is difficult to understand. As Deaver says: "Certainly, not less than one in ten adults are at some time the victims of infective hepatitis or cholangitis and cholecystitis, which, for the most part, passes unrecognized as one of the forms of indigestion."

We cannot at this time go into the method of making an early diagnosis further than to state that a careful history is of prime importance and cannot be replaced by any other measure or group of measures. In a physical examination, the palpation of the gall-bladder region, with the patient in the sitting position in front of the examiner, with the palpating fingers of the right or both hands hooked under the right costal border, frequently discovers when the liver is depressed, both by position and by the inspiratory movement of the diaphragm, localized areas of tenderness not evident by the usual method of examination. The findings by the Lyons' test may be of value to the experienced worker, but as performed and interpreted by the average physician, nurse, or laboratory worker, are apt to be misleading. The recent proposal by Graham to render the gall-bladder radiographically dense by the intravenous injection of tetrabromophthalein may be of value in the exceptional case, but cannot be adopted routinely. Finally, we may suggest that, if the large group of cases now uncritically classed as "indigestion" of indefinite type were considered as cholecystitis until proven otherwise, fewer and less serious errors in diagnosis might be made.

Second. Accepting the diagnosis of cholecystitis, we wish to prevent, if possible, further infection of the hepato-biliary zone from any focus elsewhere in the body. To this end, teeth, tonsils, sinuses, lungs, genito-urinary tract, and intestinal tract must be carefully scrutinized and all the necessary measures instituted. Radicalism in this connection we feel is indicated.

Third. Recalling that the character of the bile is dependent upon the integrity of the liver cells and the composition of the portal blood, it is evident that we must endeavor to so regulate the gastro-intestinal function that the portal blood may be as free from toxic material as possible, and from overconcentration of any of the normal products of digestion. We have little actual knowledge of these processes, but it is clearly indicated to avoid poorly balanced diets and those with chemically mechanical or toxically irritating properties and to regulate bowel function by the diet if possible, or by proper laxatives if necessary.

Fourth. The correction of overconcentration of

one or more of the bile constituents is still to a very large extent beyond our power to control. In the case of cholesterol, however, there is evidence to show that, by decreasing the exogenous supply, we may decrease the amount in the blood serum and bile, and presumably thus decrease any existing tendency for it to precipitate out. The cholesterol containing foods are still not agreed upon, but the yolk of egg, cream, butter, and animal fats are most under suspicion and should, therefore, be restricted. The concentration of the bile salts and bile pigments may to some extent be controlled by overcoming any existing constipation, and thus preventing excessive absorption of these substances from the intestinal tract and their return to the liver. The question of dilution of the bile by abundant fluid intake rests on doubtful experimental ground, but is a thoroughly justifiable procedure. Recalling, however, the concentrating property of the gall-bladder, it is evident that prevention of biliary stasis is our most vital problem. If the influence of the acid reaction of the gall-bladder content in preventing precipitation of cholesterol, calcium carbonate and calcium bilirubinate is confirmed, it may eventually be possible to control this reaction by suitable drugs.

Fifth. The elimination of existing infection in the hepato-biliary system is the goal of all our efforts. We have little information regarding the frequency of spontaneous resolution of infections in this region, but, as has been said, it is undoubtedly true that infection here as elsewhere in the body, if not too severe or resistant is gradually overpowered by the forces of immunity. On the other hand, there is abundant evidence of the most remarkable persistence of many biliary infections with the resulting pathological changes in liver, gall-bladder, biliary passages, and pancreas. Probably the prime reason for the persistence of these infections is the intermittent and incomplete drainage of the biliary system, especially the gall-bladder, with the resulting "back pressure, stagnation and alternating distention and contraction, factors which in every hollow viscus are strongly hostile to the eradication of infection."

Reasoning from the general knowledge of the treatment of infection, four procedures suggest themselves: 1. Drainage. 2. Anti-bacterial drugs. 3. General and special measures to increase the resistance of the patient. 4. Extirpation of the diseased tissue.

Proper drainage with the relief of back pressure, stagnation and alternating distention and contraction will in suitable cases free the hepato-biliary system of infection, provided it can be maintained for a sufficient period of time.

Medically, our efforts to improve biliary drainage have until recently been most questionable, and consisted of: 1. The more frequent administration of food to call forth the normal stimuli. 2. Exercises. 3. The intake of large amounts of water. 4. The administration of so-called cholagogue drugs. There can be no objection to the use of the first three methods, but their effect on biliary drainage, especially in the presence of gross pathological changes, must be extremely slight.

As for the cholagogues, we now know that bile and bile acids are the only substances that decidedly increase bile secretion, although salicylic acid and

olive oil have a less definite effect. However, it must be borne in mind that our object is not primarily to increase the secretion of bile, but to hasten its elimination from the biliary system. It is, therefore, possible that the drugs usually spoken of as cholagogues, such as aloes, rhubarb, the mercurials, podophyllum, and nitro-hydrochloric acid act to decrease bile stasis by depressing the tone of the sphincter of Oddi. Another action of these substances which may be of value is the possible decreased concentration in the bile of the bile pigments and bile acids through their increased elimination in the stool. However, even combining the true and false cholagogues, the drainage of the biliary system is far from ideal, although at least temporary clinical improvement may follow their use.

The introduction of the Lyon-Meltzer method has given us a non-surgical method of draining the biliary system, which is a decided advance over our previous medical methods. This method consists of the introduction of a solution of magnesium sulphate directly into the duodenum, following which there is normally a return flow of bile, the first, or so-called "A" bile, being light yellow and coming from the ducts, the second, or "B" bile, being much darker and apparently coming largely from the gall-bladder, and the third, or "C" bile, being again light yellow and apparently coming directly from the liver. There has been much discussion regarding the relative merits and demerits of this method, but in properly selected cases there is no doubt that treatment is followed by decided clinical improvement which is associated with a corresponding improvement in the gross and microscopic appearance of the bile and, in some cases at least, an improvement in liver function, as evidenced by an improved phenoltetrachlorophthalein excretion. It must be admitted that this method, when applied two or three times a week, or even when the tube is continuously kept in place and the stimuli frequently applied, falls far short of complete drainage. On the other hand, it must be recognized that this method may be persisted in for relatively long periods, so that in cases uncomplicated by stones, adhesions or too extensive pathological changes, there may be a gradual return to more normal function and the eradication of existing infection. The objections to the method are that it is time-consuming, more or less disturbing to the patient, although very rarely to a decided degree, and that the results, especially in the advanced cases, are questionable. However, when results by the other methods of treatment are analyzed and it is recalled that this method carries no operative risk, it seems right to try it for a reasonable period in suitable cases before proceeding to more radical measures.

Surgically, biliary drainage has been obtained by various operative procedures, the majority of which connect the gall-bladder or ducts with the exterior of the body. In these operations drainage is maintained for from ten days to six weeks. This has been sufficient to eradicate the existing infection in a large percentage of the cases, but a return of symptoms has been so frequent that drainage operations have been largely superseded by cholecystectomies. Presumably, the failures have been due to too short a period of drainage in the presence of extensive tis-

sue infection or to a possible reinfection from some untreated focus.

Attempts to eliminate infection of the liver, gall-bladder and ducts by the use of anti-bactericidal drugs has as yet met with little success. Some have advocated the use of hexamethalamine, especially in association with the salicylates. However, as our present conception of the action of this drug is that it liberates formalin in an acid media, we should expect no effect upon infection in the tissues or the common duct bile, and only a questionable effect in the gall-bladder bile. Certainly, more convincing experimental evidence is necessary before accepting this measure.

The recent work of Young and his co-workers on the intravenous injection of mercurochrome and gentian violet opens up a promising field for investigation. They have apparently demonstrated striking anti-bactericidal effects for these drugs when injected intravenously in 5 mmg. per kilo doses. The mercurochrome was especially active in colon infections, the gentian violet in staphylococcus infections. We have demonstrated the presence of both these materials in considerable concentration in the bile in from 10 to 30 minutes following intravenous injection. It is thus evident that they are excreted by the liver, and it is not unreasonable to hope that they may favorably influence infections within the tissues, as well as in the bile. Experimental work is now in progress along these lines.

Much can be done by the use of general and special measures to aid in the reduction of existing infection in the hepato-biliary zone. First among these is mental and physical rest, combined with or followed by moderate exercise and heliotherapy. The use of autogenous vaccines prepared from the organisms recovered from the bile obtained by the Lyon method may be of value, provided such cultures do not represent mere mouth contaminations.

Finally, the reduction of infection by the surgical removal of infected tissue is a well-recognized and accepted method. However, as has been shown, in chronic cholecystitis we are not dealing exclusively with an infected gall-bladder, but with a diffuse infection involving the liver, ducts, gall-bladder, pancreas, and associated lymphatics. It is clearly impossible to remove all this infected tissue, and yet a partial removal without drainage of the remaining portion would hardly seem to meet the requirements. Yet this is what is apparently done when a cholecystectomy is performed, so that rather than being surprised that some cases are not cured after cholecystectomy, it would seem more logical to be surprised that any cases are cured. The facts of the situation seem to be about as follows: Infection once established in the hepato-biliary system persists because of poor drainage, the drainage of a diseased gall-bladder is by far less satisfactory than of the remaining parts of the system, and infection is, therefore, more persistent in the gall-bladder. Graham has shown that the gall-bladder can infect the liver as well as that the liver can infect the gall-bladder, and he believes that in chronic cases there is a vicious circle established. Thus, if under favorable conditions the liver has rid itself of existing infection, it may at a later time, under unfavorable conditions, be reinfected from the residual infection in

the gall-bladder or the process may be reversed. By the removal of the gall-bladder, we remove the most susceptible portion of the biliary system and leave the remainder of the infected system to rid itself of its infection as best it can. Clinical results indicate that this occurs in a fairly large percentage of cases. Why? Apparently, because in these the drainage of the remainder of the biliary system is sufficient to allow the natural processes of immunity to overcome the infection.

The success of these natural processes of immunity in overcoming the infection depends upon the virulence and extent of the infection, the resistance of the patient, but especially upon the amount and character of tissue change. The more extensive the tissue damage, the more persistent the infection. As for the factor of drainage, ordinarily the surgeon leaves this entirely to nature. After cholecystectomies, there is a dilatation of the extra hepatic ducts because of the resistance offered by the sphincter of Oddi. However, as the ducts have no concentrating function, this dilatation is not sufficient to care for the bile secreted in the inter-digestive periods and eventually an insufficiency of the sphincter occurs. Possibly the completeness of clinical cure depends, to some extent at least, upon the completeness of the sphincter incompetence and the resulting free drainage of the biliary system. Other factors which may hinder complete recovery after cholecystectomies are the narrowing of the ducts by adhesions, with the resulting tendency to bile stasis and also the persistence of infection in a dilated stump of the cystic duct, from which reinfection of the entire system may occur.

Sixth. If biliary stasis is the result of mechanical obstruction, either by stones or adhesions, surgical treatment is clearly indicated. Also, as the presence of stones, even in the absence of obstruction, favors the persistence or recurrence of infection and constantly holds a threat of acute surgical complications, their removal should be advised.

Seventh. General measures to increase bodily resistance have already been discussed.

CONCLUSIONS

What, then, is to be our plan of treatment in the individual case? First it is, or should be evident that there is no rule of thumb to be followed routinely, and also that it is not primarily a question of medical treatment as opposed to surgical treatment. We have these various measures at our disposal, and our worth as physicians rests upon the care and judgment displayed in the choice of methods for the individual case. Many factors, sociological as well as clinical, have a bearing on this choice. As a general plan, the uncomplicated case of cholecystitis, after a complete diagnostic survey, should undergo a period of careful medical supervision, during which time focal infections are radically removed, gastrointestinal function carefully regulated, diet supervised, rest, exercise and general hygiene insisted upon; drugs administered as indicated, where possible, non-surgical drainage of the biliary tract carried out and, in special cases, autogenous vaccines used. If, after a sufficient period, not of years, such measures have failed to remove the clinical and physical evidence of cholecystitis, or if after a period of

relief there is a recurrence of signs or symptoms, surgery, preferably cholecystectomy, should be advised, as it offers a greater likelihood of permanent relief and prevention of serious complications than is offered by further unaided medical treatment. However, following cholecystectomy, medical measures should again be instituted. On the other hand, cases of acute cholecystitis, or those complicated by recurring appendicitis, gall-stones, or extensive peritoneal adhesions call for surgical measures primarily, following which the above medical measures should be used.

350 Post Street.

DISCUSSION

W. C. Alvarez, M. D. (177 Post Street, San Francisco)—Dr. Boardman has given a very good resumé of what can be done for a patient with cholecystitis. As he says, there are many cases in which, for various reasons, we will not advise or urge operation, and the problem then arises: what are we going to do in a medical way? I am afraid that I am not quite so sanguine as is Boardman about the value of the various forms of medical treatment. Some of them are based upon theories which it seems to me are unsupported by any definite studies, and the occasional success which we have with them in practice does not teach us much because the disease when untreated varies so markedly in severity from time to time.

Hence it is that I would never bother to put a patient on a cholesterol poor diet; in the first place, because its efficacy has never been shown; second, because I cannot prove that the patient hasn't a gall-bladder full of stones already; third, because so far as we know the presence or absence of stones is largely immaterial: it is the inflammation throughout the biliary tract which is the essential thing; fourth, because in order for it to be of any value the patient would have to live on such a diet for years or for the rest of his days; and fifth, because I would have no faith in his sticking to it. It is only the occasional man or woman who has enough faith, interest and moral backbone to do such a thing year in and year out.

Similarly, I never prescribe cholagogues because I cannot see how they can influence favorably an inflammatory process in the wall of a gall-bladder which is not demonstrably affected in any way by them.

As regards the Lyon technic: It was based on a physiologic misconception, and it has since been so abundantly demonstrated that the procedure does not drain the gall-bladder that it is hard to see why we should go on using it for that purpose. It may be that temporary increases in the flow from the bile ducts will aid these ducts in throwing off infection, but even then, I would like to have a little proof of the greater efficacy of the tubal over the oral administration of the magnesium sulfate before I spend hours of my time and much of my patients' money with the tube. Theoretically, the oral administration ought to work just about as well, and, practically, I have seen just as brilliant results with it as anything reported by Lyon—if results they were.

Wade H. Walker, M. D. (Pacific Southwest Bank Building, Long Beach, California)—I am delighted to have read this most wonderful paper, covering as it does the ground so thoroughly that it leaves but little for anyone to add.

Boardman is quite right. The gall-bladder walls are first infected, as a rule, instead of the mucous membrane, as is so often said. The gall-bladder has a most important function; that is, normally it secretes a mucus which dilutes strong, irritating bile on its way through the common duct to the duodenum, where it comes in contact with stomach secretions, pancreatic secretions, and aids in digesting food and preventing fermentation in the alimentary canal.

There is one point in Boardman's paper that I would like to criticize in my most humble way—that is, not to consider the gall-bladder as a reservoir for bile; it is a small oval-shaped sac, attached to the under surface of the liver, having a serous coat, a muscular coat, and a mucous membrane lining. Normally, a gall-bladder will hold

from one to one and one-half ounces; later on, after being infected, this same gall-bladder might be distended until it will hold a half-pint or more. For instance, in empyema of the gall-bladder I have seen them increase to the size of an ear of corn. In these particular cases the gall-bladder is diseased and has undergone pathological changes. Back to my starting point. A normal gall-bladder, with capacity of one to one and one-half ounces is not tankage space enough to accommodate all of the bile that is secreted normally by the liver. To the contrary, it will accommodate a very small per cent of the total output of bile at any one time, and what I mean to imply by this is, probably 1 per cent of the bile secreted by the normal liver is backed back by pressure and enters the gall-bladder for future use; there it comes in direct contact with the gall-bladder secretions, namely, mucus, is diluted, and later is emptied out through the cystic duct, into the common duct from which it came.

I remember quite well hearing Charles Mayo give a talk on infected gall-bladders, and what I have said in the preceding paragraphs bears out my experience in gall-bladder surgery, as well as what Mayo had to say in his discussion. He said that a great many surgeons objected to removing gall-bladders because it was a valuable organ when in a normal condition. On the other hand, after it became infected with la grippe germs, malaria or streptococcus infections, colon bacilli infections, etc., which destroys the mucous membrane that lines the gall-bladder or forms gall-stones, there is but little hope for a cure of such gall-bladders by a cholecystostomy.

A cholecystectomy was a little more dangerous to the patient at the time of the operation, but was well worth the cure effected in all the cases if operated in time, whereas those that were drained or had a cholecystostomy, 50 per cent of them had to be operated the second time.

We all know A. J. Oschner's opinion about draining gall-bladders versus removing gall-bladders. He says the gall-bladder is a very valuable organ and should be saved if possible, notwithstanding that a good many had to be operated the second time.

I have given you other men's opinion of the treatment of infected gall-bladder—the Mayo clinic and Oschner clinic—but that is not what you gentlemen want to hear. You want my opinion. Inasmuch as I am discussing this paper. I have a better right than most of the doctors have to discuss gall-bladder infections. I have operated quite a few, draining some, removing some, relieving some entirely; others had recurrent attacks, had to be treated medically, or have gall-bladders removed later. In December, 1913, I had my gall-bladder drained for a la grippe infection; had my appendix removed at same sitting. For seven months I had pleurisy, gall-bladder colic, indigestion, pancreatitis, and everything else a man could have pertaining to a gall-bladder infection; suffered the tortures of the damned and was unable to do a day's work in all that time. In July, 1914, I had my gall-bladder removed, on my feet in six days, all O. K. in nine days, went to work in September, and been well ever since.

I think the average surgeon should be conservative in his work, and should remove gall-bladders instead of draining them, because it takes a man of wide experience and with plenty of facilities to cure an infected gall-bladder by the drainage method. You hear some reputable physicians say they can cure gall-bladder infections by washing out the duodenum with the duodenal syphon. I believe that this is next to impossible.

Urotropin given internally in large doses is a panacea for thick and infected bile. It also will cause drainage tube tract to close more readily as an after treatment in cholecystostomy.

L. G. Visscher, M. D. (Westlake Professional Building, Los Angeles)—It is a pleasure to listen to a paper so completely covering the subject discussed in comprehensive sentences, stating definite indications.

May I be permitted to make a paradoxical statement of possible value? If drainage of the biliary system be the object, does it appear that a one-time drainage, as produced by an ordinary cholecystostomy for removal of stones, is insufficient. The usual time of drainage is from five to ten days, evidently fully inadequate to reach the proposed goal, and, aside from the removal of the stones, not productive of lasting benefit. Methods of cholecystostomy characterized by large gall-bladder incisions, or even by par-

tial removal of the gall-bladder, seem to be, in the light of this observation, of possible value.

If, however, the gall-bladder be removed, has it been demonstrated repeatedly, by those who have sufficient experience with the Lyon method, that over a period of from three to six months, no bile can be secured. This observation may be explained by the assumption:

First. That no storage facilities are left soon after the removal of the gall-bladder, these facilities, however, not only as to storage, but also as to bile inspissation, becoming established some months after the cholecystectomy in the form of dilatation of hepatic ducts and the formation of histological elements in the wall of these ducts, securing this inspissation.

Second. By the profound interference with the innervation controlling the relaxation and contraction of Oddi's muscle, leaving the muscle relaxed, the result being that the bile in continuous flow leaves the biliary system, whereby a prolonged continuous drainage of the bile passages is secured.

It gives me particular satisfaction, as an internist who loves to argue with surgeons, of recommending, in cases where thorough drainage is desired, the more radical operation of complete removal of the gall-bladder.

Charles D. Lockwood, M. D. (295 Markham Place, Pasadena, California)—This splendid paper is one of the sanest and most complete discussions of cholecystitis that I have ever heard. Every conscientious surgeon who has had a large experience with gall-bladder surgery has gone through an evolutionary process in his attitude toward the treatment of gall-bladder infections. In our early experience with gall-bladder surgery we rarely removed the gall-bladder, and I think most of the older surgeons will agree with me that our results were very satisfactory.

In looking back over my own work of the past twenty years, comprising about 100 operative cases for gall-bladder disease, I am sure that over 80 per cent of these cases were permanently cured by cholecystotomy. A recent review of some 300 cholecystotomies by Dr. Cullen of Baltimore reveals about the same number of satisfactory results. In view of these excellent results before the days of frequent cholecystectomies, and considering that these results were obtained in the most advanced and unselected cases, I feel that we should not commit ourselves to cholecystectomy in every case. There are cases of advanced liver and pancreatic infection in which I believe that gall-bladder drainage is still the operation of choice, even though it may be necessary later to do a cholecystectomy.

I think we are all agreed as to the advisability of cholecystectomy in hydrops, old thickened and shrunken gall-bladders, gangrenous gall-bladders, and certain cases of empyema of the gall-bladder, but I am sure there is still a place for conservative surgery in this field, and it requires the highest surgical skill and judgment to properly select these cases.

Doctor Boardman (closing)—In closing, I wish to express my appreciation of the kind comments of the previous speakers. However, I am a bit disappointed in Dr. Alvarez' remarks, but still feel justified in recommending in suitable cases, low cholesterol diets, bile salts, or the Lyon treatment.

As regards Dr. Walker's question of the storage function of the gall-bladder, I believe the recent work of Rous and MacMaster will thoroughly answer this.

Finally, let me again plead for an earlier recognition of chronic cholecystitis, followed by a period of systematic and sane medical treatment which, if unsuccessful, should be followed within a reasonable period by surgery.

"I have had three personal ideals: One to do the day's work well and not to bother about tomorrow; the second to act the Golden Rule as far as in me lay towards my professional brethren and towards the patients committed to my care; . . . and the third to cultivate a measure of equanimity as would enable me to bear success with humility, the affection of my friends without pride, and be ready when the day of sorrow and grief came to meet it with courage befitting a man."—Osler.

THE PROSTATIC MEDIAN BAR, COMPLICATIONS AND TREATMENT*

By MILEY B. WESSON, M. D., San Francisco

The obstructive symptoms of a small median bar and a large benign hypertrophy are the same.

When properly restricted to carefully studied, well-chosen cases, Young's punch operation is very radical and permanently curative.

A median bar once removed does not recur.

There will be no hemorrhages if (1) the operation is properly performed; (2) the patient is kept quiet; (3) water is forced, and (4) drainage is maintained.

Ten successful consecutive Young's punch operations are analyzed from the standpoint of untoward symptoms, their cause and management.

INTRODUCTION

ALL doctors, irrespective of their medical specialties, are interested in the subject of prostatism. Is it because they are all prospective operative subjects? Thirty per cent of all individuals past middle life have prostatic obstructions, though only 15 per cent seek relief from their symptoms. One-half of the obstructions consist of prostatic hypertrophy, benign or malignant, and the remaining 50 per cent are median bars. Drugs may temporarily relieve the symptoms, but eventually the services of a surgeon are required. In this special field the general surgeon is at a disadvantage. He can do a suprapubic prostatectomy as well as a trained urologist, but if the result is not good he can neither tell the reason why nor remedy the defect. Many surgeons have done cystotomies on patients, suffering with all the symptoms of prostatic obstruction, and instead of seeing an enlarged prostate gland have found a tight orifice and a small "fibrous prostate" which could not be enucleated, but had to be "cut out in pieces," with the result that the surgeon had a most trying experience, and the patient generally succumbed. It is here that the technically trained specialist possessing an extensive armamentarium of instruments and a high degree of mechanical skill in using them, acquired only by a prolonged and large clinical experience, is needed.

In preparing this paper a thorough review of the literature of the prostatic median bar was made, in order to ascertain why the punch operation that has proven so uniformly satisfactory in Hugh H. Young's hands during the past fifteen years has not come into universal use. A series of ten successful consecutive punch operations is analyzed from the standpoint of unusual symptoms and their management. Those cases that are ordinarily dismissed with the statement that "the patient recovered after a stormy convalescence" are here given especial attention. All the possible reasons for failure of the operation and the methods of avoiding disaster are elucidated.

HISTORY

The first description of the median bar and its treatment is found in the lectures delivered in 1830 by G. J. Guthrie (Fig. 1) before the Royal College of Surgeons in London. However, in 1850 Mercier,

1. The first median bar reported: "The examination after death showed nothing peculiar save the five pouches and the bar at the neck of the bladder formed by its elastic but now rigid substance, totally unconnected with the third or middle lobe of the prostate." (Guthrie.)

2. Normal vesical orifice—sagittal section of bladder and prostate.

3. Median bar with beginning undermining of hypertrophied trigon; marked trabeculation of bladder wall, and cellule formation.

4. Median bar, type I. (Young and Cecil.)

5. Microscopic sagittal section of fibrous median bar, type I.

6. Median bar encroaching on vesical trigon and causing shortening and transverse creasing, type II. (Randall.)

7. Median bar in which glandular elements predominate over sclerosis—microscopic section, type III.

8. Isolated hypertrophy of subcervical gland, type IV. (Young.)

9. Large Albarran's lobe, commonly confused with middle lobe of prostate.

10. As the result of back pressure from a median bar there occurred a hypertrophied trigon, which functioned as a dam causing incomplete retention. Splitting the

trigon did not effect a cure, and neither did several punch operations, since part of the original obstruction at the vesical orifice persisted; however, a very thorough punch operation with many cuts resulted in apparently a permanent absence of residual urine. (Young and Wesson.)

who was a voluminous writer and very aggressive, was awarded a prize of 1500 francs by the French Academie of Sciences for the discovery of the median bar, and to this day is given the credit by all textbooks, the name of the real discoverer never being mentioned. Guthrie's descriptions are accurate, yet he was robbed of the credit due him, because of his gentle retiring nature and dislike of publicity. This latter trait, as well as his two operative procedures, is well illustrated by the following extracts from his book published in 1834: "The object is to divide the bar, dam, or stricture, with as little injury as possible to any of the neighboring parts. When these are sound, as far as can be ascertained, I recommend its being done by an instrument which Messrs. Everill and Mason, of St. James' street, have made at my suggestion, being an improvement on the central perforator or lancet of Mr. Stafford, which renders it capable of cutting on the side, and of being easily cleaned. Messrs. Everill and Mason wished to call it my instrument; but as I never claimed more in any instrument than the suggestion, leaving the mechanism entirely to the artist, I have begged them to take to themselves any or all the merit which may be due to it or them." His perforator or punch would not cut the dense fibrous bars, so he advised "in the very advanced stages of the disease, when the bar is fully formed, a small perineal incision should be made on a grooved director and the bar cut with a probe-pointed, strong, but narrow knife." Sixty-seven years later Fuller redescribed this method of cutting the bar, while Chetwood changed it slightly by using an electrocautery blade—a modified Bottini operation.

ETIOLOGY

Median bars are of two general types: (1) Congenital, and (2) acquired. Young found that the histories indicated that 5.6 per cent of his cases were congenital. In the first group are included the cases,

described by Englisch, of the congenital absence of the prostate, the hypoplasia of the gland first manifesting itself at puberty with obstructive symptoms. The majority of the cases occur secondarily to some inflammatory reaction. Ciechanonski believed that there was a deposit of fibroplastic material (connective tissue) which, if beneath the mucosa of the entire bladder, caused a permanently contracted bladder, below the bladder neck caused a contraction of the orifice, or in the prostate resulted in a small fibrous prostate; while Belfield looked upon the perivesicular infections as the source of the fibroid indurations of the base and neck of the bladder. The German schools teach that atrophy of the prostate occur from various causes, and that, because of propinquity, a sclerotic bar forms at the region of the bladder sphincter. However, it is generally agreed that the median bars are secondary to infections of the seminal vesicles and prostate.

Camaro of Milan, Italy, advanced a clever theory to explain the unaccountable cases; he thinks the sources of obstructions are prostatic adenomata so minute as not to be detected by the cystoscope, but only to be felt by the finger. Fowler has described small intraurethral projecting prostatic lobes which can be diagnosed only with a cystourethroscope. The theory of retention, due to atony of the bladder as taught by Guyon and Albarran, has long been discredited.

PATHOLOGY

A median bar (Figs. 2, 3) is an obstruction involving the posterior vesical lip, unassociated with changes of an obstructive character elsewhere in the prostate, bladder, or posterior urethra.

Great confusion of nomenclature has resulted from the introduction of clinical descriptions by surgeons. Randall, by his painstaking study has clarified the field and given us an accurate classification. He described four distinct types: (1) A narrow bar

(Fig. 4) made up of firm, dense sclerotic tissue, forming an abrupt angle with the lateral walls of the vesical outlet (Fig. 5); (2) a fibrous bar encroaching on the trigon rather than on the urethra with a shortening of the trigon, due to transverse creasing (Fig. 6); (3) a glandular bar with the hypertrophic process confined to the gland acini of the posterior prostatic commissure inside of the prostatic capsule and under the sphincteric muscle which raises the posterior vesical lip into a broad obstructing bar, unassociated with visible hypertrophic changes in the lateral lobes. It is a prostatic hypertrophy associated with inflammatory sclerosis (Fig. 7); and (4) isolated hypertrophy of a subcervical gland (Fig. 8), commonly called an Albarran's lobe (Fig. 9).

SYMPTOMS

The general symptoms are those of urinary obstruction and are the same as of hypertrophy of the prostate. If the urinary retention is not relieved there is failing health, with drowsiness, headache, gastro-intestinal disturbances and, eventually, nocturnal thirst.

Hugh H. Young, in a personal communication, states that an analysis of his 355 cases showed that in the punch cases pain was as prominent a symptom as was retention in the cases of hypertrophy. The symptoms for which he performed the punch operation were in their order of frequency as follows: (1) Frequency of urination, 82 per cent; (2) pain, 53 per cent; (3) difficulty, 50 per cent; (4) small stream, 42 per cent; (5) weak force, 40 per cent; (6) urgency, 25 per cent; (7) occasional complete retention, 11 per cent; (8) incontinence, 8 per cent; (9) sudden stoppage, 8 per cent; (10) complete retention, 7 per cent; (11) urination incomplete, 5 per cent. The painful symptoms are distinctly more frequent, more annoying and distressing than in prostate hypertrophy; not infrequently they overshadow everything else and the patient seeks relief on account of the irritation. The location of the pain was: (1) Urethral, 21 per cent; (2) bladder-neck, 18 per cent; (3) end of penis, 15 per cent; (4) perineum, 14 per cent; (5) suprapubic, 12 per cent. Sexual symptoms were practically negligible and occurred for the most part in patients past middle life.

There is no relation between the size of the obstruction and the amount of retention. The function tests show kidney impairment to be as great as in cases of prostatic hypertrophy, hence they must receive the same careful preliminary treatment as do prostatectomy cases. The worst complications (Figs. 10 and 11) are often secondary to small bars that have been overlooked.

DIAGNOSIS

Median bars must be differentiated from hypertrophy of the prostate, organic stricture of the urethra, papilloma, and spinal cord lesions. The history is of importance, and as a rule those cases above 55 years of age are suffering from hypertrophy, while the younger ones have bars. In Young's series one patient was 7, twenty were under 30, and five were over 80 years of age. Hematuria is common in benign prostatic hypertrophy and rare in median bars. In bars the prostate is of normal size and con-

11. Hydronephrosis (bilateral) secondary to a median bar.

sistency on rectal palpation. Sounds of large size often pass with ease, although a uniformly contracted, tight orifice may resist the passage of a very small one. When viewed through a suprapubic opening the vesical orifice may appear normal, but when an attempt is made to dilate it with a finger-tip there is found a tight thickened ring which offers a firm resistance. Since the introduction of the Wassermann reaction, spinal cord lesions have become of minor consideration. However, with the cystoscope, cases of tabs have been diagnosed where the serological test was negative.

The diagnosis of a median bar is made upon four positive findings: (1) Residual urine; (2) trabeculation of the bladder wall; (3) slight lateral clefts, and (4), with the finger in the rectum and the cystoscope in the urethra, there is a distinct "jump" as the beak of the instrument, which is being gradually withdrawn, passes over the vesical lip.

OPERATION

Only four types of operation should be considered: (1) Young's punch; (2) cautery punch; (3) sphincterotomy, and (4) fulguration. The perineal and suprapubic procedures are unnecessarily mutilating and dangerous.

The punch method is, in principal, that described by Guthrie in 1830, but it remained for Young to perfect the instrument, define the group of patients suffering from obstruction at the vesical neck, to which the punch is applicable, and describe the method (Figs. 12-19) and results to be expected in types of cases. In 1909 he did his first punch operation, and the method, with very few changes, has become standardized. When properly performed upon selected cases, beautiful and brilliant results can be obtained.

The cautery punch devised by Young in 1911 and

12. Young's punch in operation. The outer tube has been withdrawn far enough to entrap the median bar in the fenestra, as indicated by a checking in the flow of the fluid. The hands of the operator are shown ready to push the inner tube home. (Young.)

popularized by Caulk in 1920, consists of a slow-burning, heavy knife in an irideo-platinum sheath. Hemorrhage is stopped by the heat, so that no catheter is required for the drainage, and the operation can be done in the office. Caulk has had no local or systemic reactions, although others have not been so fortunate.

"Sphincterotomy per urethram" was described by the late J. T. Geraghty in 1922, as a simple office procedure which was rarely followed by even blood-stained urine. The instrument is a modified Young's punch, the circular knife being replaced by a wedge-shaped concave blade, so that a single cut is made through the bar instead of removing a section. This is the method used by Guthrie, who, in describing his operation, said: "The knife being projected just as the instrument is felt to be passing the bar, will cut it; and if, after it has just passed into the bladder, it will be withdrawn, the little knife, in coming back, will enlarge the original cut. If the bar be thin or narrow, I have no doubt of the possibility of dividing it in this way without doing mischief; and in two cases in which I tried it, I have reason to believe the object was effected." I have not used the sphincterotome, but a personal communication from E. W. Beach (Sacramento) states that in a series of seven cases he found it very satisfactory and efficacious. In three cases he used no retention catheter, but in the remaining four cases it was necessary—one hemorrhage being so severe as to necessitate two blood transfusions.

Bugbee, in 1911, reported nine cases treated with the Oudin current one-quarter inch spark, direct contact, burning until the hydrogen bubbles ceased to form. Three to six treatments were required to cut the bar, and there was no bleeding and no retention.

Fulguration with the D'Arsonval current has been successfully used. However, the burns are deep and secondary hemorrhages tend to occur several

weeks after the patients are cured and have returned home.

UNUSUAL SYMPTOMS AND COMPLICATIONS

A series of ten consecutive punch operations is analyzed from the standpoint of untoward symptoms, their cause and management. The operations were performed upon private patients ranging in age from 40 to 75, the average age being fifty-eight and one-half years. Although a history of gonorrheal infection was not elicited from each one, an examination of the prostatic and seminal vesicle secretion showed clumps of pus in every case.

The only anesthetic was an urethral injection of 4 per cent novocain, and in all of the cases the operation was painless. It was a routine procedure to have the coagulation time of the blood determined before operation, and to give a hemoplastic preparation in the operating room. In view of the recent report of the Council on Pharmacy and Chemistry of the American Medical Association, warning against the indiscriminate use of such preparations because of the danger of fatal anaphylaxis, this step will have to be guarded in the future. A hypodermoclysis of 3000 cc. of saline was given each patient upon the return to his room from the surgery, and a minimum fluid intake by mouth of 5000 cc. was maintained throughout his hospital stay.

Caffeine sodium benzoate, grains III (hypo), as a routine emergency order (to be given by the nurse) demonstrated its value in one case. The pulse rate of a patient with ventricular extra-systoles dropped to less than 40, and was barely perceptible shortly after his return from the operating-room, and, as sometimes happens, just as all the doctors had gotten out of call; a half-hour later when I saw him he was in perfect condition.

Four of the cases had large vesical diverticula. In two cases these were not removed, as the general condition of the patients did not warrant the risk,

13. Longitudinal section showing a typical median bar elevated above the trigon without enlargement of the prostate. (Young and Cecil.)
14. The punch instrument has been introduced well into the bladder and the inner tube drawn upward, thus opening the fenestra through which urine begins to escape. The median bar is seen depressed by the shaft of the instrument. (Young.)
15. The cutting inner tube is excising the median bar. (Young.)

16. The cut is completed and the section is in the tube. (Young.)
17. Sectional view showing the removal of the excised mass of prostatic tissue with the urethroscopic clamp. (Young.)
18. The completed operation. (Young.)
19. Drainage of bladder with a large catheter, 30 F coude, after removal of the prostatic bar or contracture. (Young.)
20. Cystogram showing two large diverticula, secondary to a median bar.

but in the other two, diverticulectomies were done. Young's suction method was successfully used in one case (Fig. 20), but failed in the other, as the pouch was attached deep in the perineum. In this case there was a complete retention, the residual urine being 1000 cc. The stones present (Fig. 21) were removed by means of a sponge stick; a retrovesical dissection was made and the sac (Figs. 22, 23) freed, except at its apex, invaginated and removed. The open punch operation, supplemented by an incision with a scalpel, was performed in both of these cases.

The number of cuts made in the routine operation varied from three to twelve; the first was made

posteriorly (great care being taken not to catch the hypertrophied interureteric ridge) and the punches ceased when the vesical orifice was fully dilated, as shown by the failure of the punch to engage. After three cuts, great care must be used, for, if the sheath is not firmly engaged, there is danger of it slipping just as the punch is sent home, and the cut will be made in the urethra. Swinburne reports the punch slipping into the pendulous urethra and hanging by a bent tooth, so that he had to do an external urethrotomy to remove it. Clipping off the verumontanum is not an uncommon procedure, and is undoubtedly responsible for the disturbances of sexual function which sometimes follow this operation. The

21. Median bar causing complete retention and a large diverticula. A catheter in the left ureter is apparently in contact with a calcified lymph gland; the second catheter points to the stones in the bottom of the diverticulum.

22. A cystogram that conceals the diverticulum, but exposes the calcified lymph gland.

23. A diverticulogram made by filling the bladder with air after the patient had voided.

specimen removed generally consists of fibrous tissue, smooth muscle fibers, and gland acini; but if the anterior bite is sufficiently deep it may get striated muscle (Fig. 24).

24. Schematic view of the muscle of the bladder orifice, showing how deep a cut would have to be made in order to include striated muscle fibers, E. V. S.

Just as important as the mechanical excision of the bar by the punch is the placing of the catheter. The tendency is to use too small a catheter and, unless specifically ordered, the dealers supply those with only one eye, and if this happens to lie against the trigon there will be no drainage. A 30 F. Coude catheter with two eyes should be used. If it is properly located and firmly fixed all hemorrhage will stop within a few hours. In this series, clear urine was passing in all cases in from two to twenty-four hours.

There was one secondary hemorrhage, because of a dull punch, the inadvertent use of too small a catheter (29 F.) and with a single eye, and some poor adhesive plaster that did not hold the catheter in position. The patient's urine was clear at the end of twenty-four hours, but because I had used a poorly sharpened punch which tore off a large piece of mucosa I thought best to leave the catheter an

additional twenty-four hours. During the night the catheter ceased to drain, due either to the single eye rotating against the trigon, or slipping into the prostatic urethra. A poorly trained orderly advised the patient to stand by the side of the bed and strain, which he did, and eventually he succeeded in starting a stream, but it was blood and not urine. When I saw him he announced that he was going to die, and confessed that he had come to the hospital expecting that result. The catheter was removed and a metal clot-aspirator substituted, but the oozing continued. Although his red blood count was 4,340,000, a blood transfusion was done because of his mental condition rather than his physical; two days later this was repeated. At the end of five days the urine was clear and the "clot sucker" was removed. He then developed a toxic delirium of a religious type, and became so violent that he had to be restrained. The patient had been trained as a priest, but became an agnostic; his attack was precipitated by the actions of his religious male nurse trying to reconvert him, and was ended three days later, when a priest, who was called after midnight, upbraided him for his "thoughtlessness in disturbing a Father's rest," and returning after daybreak continued the scolding. This brought back his old hatred for the Church, and at 8 a. m. he was mentally normal. He left the hospital fourteen days after operation, having gained twenty-two and one-half pounds. I might say in passing that I never knowingly operate upon a patient who thinks he is predestined to die from the operation.

Many of the commercial punches should not be used, as they do not fit snugly and tend to tear the tissue rather than cut. I use one given me by Dr. Young and made by his mechanic from non-rustable steel. It is routinely sharpened by an expert immediately before use. This instrument broke while in use in one case just as it became firmly engaged; in cutting through a very fibrous bar, considerable force was used and the flange became unsoldered from the sheath. With the aid of a pair of Lane bone-forceps and some strips of adhesive plaster, the shaft was held and the operation successfully concluded.

The urethral spheroids described by Fowler, I found in a man of 54 who also had a bar. The bar was removed, 60 cc. of residual urine disappeared, and a toxic man became active and alert.

Following the removal of the catheter, after the urine has become clear, there is no difficulty in voiding for several days; then there may be sufficient edema of the vesical neck to require catheterization. Great care must be used or a secondary hemorrhage will be started. A No. 18 silver catheter with a short beak is ideal. One of my patients developed a retention at night, and a new intern used a No. 12 silver catheter with a long curve, which penetrated the urethral mucosa and resulted in a suburethral infiltration. Atypical symptoms of pneumonia followed, and it required considerable search to find the cause of the rise in temperature and chills.

The patients cannot be dismissed as cured when they leave the hospital. The bar is gone, but not the symptoms. They require the passage of sounds, instillations, hydraulic bladder distensions, etc. The posterior urethritis and cystitis does not disappear along with the bar, and the patient wants relief from his symptoms. However, treatments should be postponed for six or eight weeks. Incontinence is an unknown complication.

SUMMARY

Guthrie noted that the punch operation was of little value in cases of benign hypertrophy, since the groove through the hypertrophy allows the adenoma to swell up into the opening. However, it has proven of great value in many cancer cases. Cases of retention, due to a complication of a median bar and a spinal lesion, may be cured by this method.

The punch operation, as perfected by Young, is not a palliative procedure, but is a radical operation, and when properly performed upon suitable cases is 100 per cent efficient. It is exceedingly technical, requiring a very painstaking preliminary study and close attention to details during and after the operation. It should never be performed in a hospital where there is not a careful enthusiastic resident and an efficient orderly.

Each case is a separate problem, and if watched closely, so as to anticipate complications, the patient will make a rapid and uneventful recovery and with a brilliant result. In the hands of a careless staff I can conceive of no operation with so many elements of potential danger. I have never seen a case of hemorrhage where I thought cystotomy was indicated, and Young states that he personally has never done a secondary suprapubic operation upon a punch case for hemorrhage.

In Young's series of 355 punch operations seven cases died in the hospital some time after the operation, but only one death was directly due to the procedure (a cut trigon). Even if all the deaths are counted, the mortality is less than 2 per cent. "One may, therefore, say that when we consider the age of many of these patients and the serious complications which were often present, the punch operation is indeed a very benign procedure."

CONCLUSIONS

1. The median bar and its treatment were first described by Guthrie in 1830.

2. The obstructive symptoms of a small median bar and a large benign hypertrophy are the same.

3. The disturbances of micturition in a man under 55 years of age are generally due to a median bar, while in older men they are probably due to hypertrophy.

4. When properly restricted to carefully studied, well-chosen cases, Young's punch operation is very radical and permanently curative.

5. A median bar once removed does not recur.

6. There will be no hemorrhages if (1) the operation is properly performed; (2) the patient is kept quiet; (3) water is forced, and (4) drainage is maintained.

7. The three common causes of hemorrhage are: (1) the tearing of the mucous membrane by a dull knife; (2) the use of a catheter with one eye, which results in straining because it is not properly placed to maintain drainage; (3) a catheter so small as not to fit snugly against the cut surface and thereby hasten clotting.

8. A slow blood coagulation time is a positive contra-indication for a punch operation.

9. In all cases of persistent hemorrhage or shock, transfusion is indicated before a cystotomy should be considered.

10. The cystoscopic diagnostic signs are: (1) Residual urine; (2) trabeculated bladder; (3) lateral clefts; (4) the "jump" felt by the finger in the rectum pressed against the slowly withdrawn cystoscope in the urethra as the beak passes over the vesical lip.

11. Ten successful consecutive Young's punch operations are analyzed from the standpoint of untoward symptoms, their cause and management.

12. The punch is a dangerous instrument in careless, incompetent hands.

N. B.—I desire to express my appreciation to Dr. Hugh H. Young and William P. Didusch for the use of their original drawings.

1275 Flood Building.

Making Our Remedies Safer—The American Pharmaceutical Manufacturers' Association recently adopted a "Declaration of Belief," which sounds a new and encouraging note: "We believe," says the Association, "that it is the unquestioned obligation of each and every pharmaceutical manufacturer: (a) To manufacture preparations only under proper conditions and of established value, pure and accurate in composition, and true upon, and to, their label; (b) to label, advertise, and merchandise such preparations only in a manner wholly free from misrepresentation of any kind, in complete accord with both the spirit and terms of the applicable laws, and in entire harmony with the highest standard of commercial morality and ethics."

"The trouble," believes the New York Medical Times, "is that the big cities are full of people who were intended in the phylogenetic nature of things to work in a simple way upon a small area of the earth's surface without any undue strain upon the brain or nervous system. Our industrial and profit-seeking civilization takes these peasants, schools them under painful pressure (for them), and then subjects them to a vocational grind that takes them nowhere, without even a pension at the end of the senseless gamut."

DEVELOPMENT AND RE-ESTABLISHMENT OF BREAST MILK BY USE OF DR. ABT'S ELECTRIC BREAST PUMP

A PRELIMINARY REPORT *

By EARL M. TARR, M. D., *Los Angeles*

Indications for and results obtained by the use of the pump both in developing and re-establishing breast milk. The importance of emptying the breast as a sure method of prolonging the milk supply is strongly emphasized.

Several illustrations.

Healthy discussion by A. J. Scott Jr., Los Angeles; Angus B. Cowan, Fresno; Clain F. Gelston, San Francisco; Robert G. Sharp, San Diego.

MY THEORY that the new-born infant is practically never able to completely empty a full breast and that a breast will function in direct proportion to the amount of stimulation which it receives, is reasonable and will eventually be accepted as a fact. When this point is definitely settled and its significance fully appreciated, more consideration will be given the mechanism of nursing and more infants will be given breast milk over a much longer period than at the present time.

Development of breast milk should begin THE DAY THE BABY IS BORN. There can be no question regarding the logic of this statement, and yet very few of us actually begin our real work until there is a definite shortage of food. To presume that the infant is going to be able to furnish enough stimulation to start a breast going properly and keep it functioning satisfactorily for seven or eight months simply means that *weaning* will automatically take place long before it should. It seems advisable, therefore, to study the infant at breast, and if he is unable to completely empty the breast at each nursing, then added stimulation may well be considered.

The late Dr. Sedgwick did more, perhaps, than any other one man to stimulate us to thought and action regarding the best means of developing and maintaining breast milk. Dr. Abt has always taught that thorough emptying of the breast at each nursing is absolutely necessary if we hope to keep the organ functioning adequately throughout the normal period of lactation. I believe that I am one of the first to specifically state that practically no new-born infant is PHYSICALLY able, during the first few weeks of life, to empty a breast, and that added stimulation should be given the breast *as soon as the baby is born*.

"Expression," as advocated and taught by Sedgwick, has been productive of amazing results, and thousands of infants have been saved because proper and sufficient food was made possible for them. Ulysses Moore, in his work in France and Belgium, and Portland Oregon, clearly demonstrated that development and re-establishment of breast milk was the most practical way to supply safe food for the starving infants under his observation. In private and clinic practice in this country, he insists that "all healthy mothers can keep their breast milk indefinitely if the breasts are properly stimulated."

The electric breast pump which Dr. Abt has per-

fectected will not, in my opinion, discourage the practice of hand expression. Indeed it will serve to lay the foundation and pave the way so that expression will be more generally practiced. This pump is a mechanical contrivance, electrically driven, and operates on the same principle as the milking machine used in the dairy. This electric pump will be found far more useful in the maternity division of the hospital than elsewhere, and I feel reasonably sure that it should be used there rather than sold to the mother for home use. Hand expression can be done by the mother after she leaves her lying-in bed, and will be found altogether satisfactory. Time will not permit detailed description of the pump. During the past year I have used it extensively and have studied results impartially. I must thank the obstetricians for their excellent co-operation without which even a preliminary report at this time would be impossible.

ADVANTAGES OF THE ELECTRIC BREAST PUMP

1. The pump is safe and easy to operate, and a breast may be emptied in three or four minutes.
2. One pump will do the work of six nurses.
3. Improper technique on the part of inexperienced nurses who practically never "express" properly will be largely overcome.
4. Engorged breasts, in which the nipple is short and difficult of manipulation, can be relieved or emptied quickly and without pain. The relief to the mother is immediate and complete.
5. Premature infants will be assured of their intended food, if the pump is used on the mother until her milk supply is fully established.
6. When used on the mothers in a maternity ward, an abundance of breast milk will always be on hand for delicate or premature infants.
7. The use of the pump will relieve mothers of the tedious, tiresome, and often painful method of hand expression which is still practiced in some hospitals by the sick mother at the request of her physician.
8. Breast stimulation can be started as soon as the baby is born, and once the mother realizes that her babe cannot give sufficient stimulation, she will readily see the logic of expression and will be eager to practice it after returning home.
9. Fissured nipples heal promptly when the pump is used and the infant kept from the breast for a short time.

IMPORTANCE OF PROPER MILKING TECHNIQUE

It is to be remembered that mothers are entitled to all the consideration we can give them, and their mental, as well as physical, comfort should be carefully planned. You will find, when you first use the pump, that in some patients curiosity, timidity, and actual fear will be encountered, and these conditions must be carefully eliminated.

Some of the important points in connection with successful use of the pump are as follows:

1. Assure the mother that the pump will not hurt when applied to her breast.
2. Allow her to experience the sensation of suc-

* From the Department of Research the Anita M. Baldwin Hospital for Babies.

Figure I.—Re-establishment. Dry breasts for nine weeks. Dr. Abt's electric breast pump used forty times before results were assured.

Figure II.—Same case one month later, at which time breasts were producing 20 ounces daily. Pump used 200 times.

tion by holding the shield over the palm of her hand. This will give her an exact idea of just how it will feel to the breast.

3. Always start with the suction at zero and very gradually increase. This is necessary to "draw out" the nipple and when slowly and painlessly done will avoid frightening the mother. As she becomes accustomed to the sensation, the vacuum may be increased.

4. Careful selection of a proper shield, or glass nipple, is essential. Long nipples require a larger shield than short nipples, and it is necessary to apply the shield to the nipple in such a way that the openings in the nipple do not come up against the sides of the glass shield. This would, of course, shut off the free flow of milk and would give discouraging results.

5. Forbid demonstrations on a patient until she is thoroughly familiar with the pump.

6. The container which is to receive the milk as it escapes through the rubber valve must be large enough at the mouth to allow the valve to empty freely. A clean medicine glass or a clean glass tumbler is satisfactory. The ordinary small-necked nursing bottle is the container we use.

DEVELOPMENT CASES—GROUP 1. SIXTY-TWO CASES

Sixty-two studies make up this group. Of this number, there were forty-eight spontaneous deliveries, one breech, one version, eight low forceps, and two Caesarian sections. The birth weights ranged from 5 pounds 3 ounces to 10 pounds 9 ounces, and the number of males happened to be exactly the same as the females. All of these babies left the hospital weighing more than their birth weight. (This is due, in part, to the fact that none of them were allowed to experience the usual "physiologic loss" for more than sixty hours). They were all given a 15 per cent carbohydrate solution until the milk flow was well established, were nursed at three and four-hour intervals, and were also given the milk obtained by pumping. No nursing period was for longer than

twenty minutes and, when possible, we kept them at the breast not more than ten minutes.

Among the mothers were four who had never been able to nurse previous children. In spite of their belief that it was utterly useless to attempt to develop milk, they all became excellent producers and went home with more milk than the infants could use. Three of the mothers gave a history of breast abscesses at previous times, and the breasts had been given up as worthless. All of these mothers developed quite all the milk they needed.

Thirty-six mothers were primiparae, and twenty-six were multiparae. Owing to the fact that they were the patients of several doctors, it was impossible to handle all of them the same. The pump was used not less than five times daily nor more than seven times, and it was used regularly from the *day of delivery to the last day in the hospital*.

COMMENT

The results were uniformly good. All breasts responded well, but some were slower than others. No sore breasts or breast abscesses developed. Primiparae, in this group, did a little better than multiparae, and I lay this principally to the fact that these women are often in a better physical state than women who have borne several children. This is by no means a rule, but simply an observation. Practically all of these patients have been under observation during the past six months. Clinic cases have been more difficult to follow than private cases, but those who have reported regularly have done better than we had expected. So near as we can learn from the data obtained, about 90 per cent of these babies have had breast milk throughout their first six months. We hope to follow these cases for another three or four months, and then draw our final conclusions.

RE-ESTABLISHMENT CASES—GROUP 2. SIXTEEN CASES

Naturally, the re-establishment of breast milk is far more difficult than the comparatively simple task

Figure III.—Development. Right breast nursed by infant. Left breast pumped with Dr. Abt's electric breast pump. Infant one month old.

Figure IV.—Appearance of breasts of primiparae after pump used two weeks to develop milk. First picture about like Figure I. Pump applied eighty times.

of its primary development. Most of the mothers in this group had been dry, or practically so, from two to nine weeks, and the electric pump was used, not because I consider it greatly superior to hand expression, but because it would do the work much quicker. These women are all difficult psychological problems and require careful management. The chief difficulty is that most of them refuse to believe that the dry breast can be made to resume function and this, of course, must be definitely settled in their minds before any results can be expected. Detailed directions regarding their daily mode of life and what is expected of them must be outlined and explained with considerable minutia. They are taught how to use the pump and are asked to report each twenty-four hours.

The shortest time necessary to re-establish milk in this group was nine days. This woman had been dry for five weeks. The pump was used six times in each twenty-four hours, and on the second day she got a few drops. This encouraged her, and the belief on her part that she was going to be successful was the best galactagog imaginable. She went right up to 16 ounces in the first week, and a week later was producing 22 ounces daily.

The longest time required to re-establish milk was thirty-eight days. This woman had been dry for ten weeks, but she worked the pump faithfully and on the sixth day was rewarded with a few drops of watery fluid. She had applied the pump just forty times during the week. Her production then became regular but very slow up to the twenty-eighth day, when she obtained 12 ounces in six pumpings. On the thirty-eighth day she got 21 ounces and kept this amount during the next four months.

SUMMARY

This is a preliminary report of my experience with Dr. Abt's electric breast pump in developing and re-establishing breast milk. At present I am encouraged and rather enthusiastic, and believe that the pump will prove exceedingly valuable in the maternity hospital. Certainly, it is worthy of trial be-

cause it does no injury to a breast and, in my experience, has helped develop and re-establish milk easier and more promptly than hand expression.

2007 Wilshire Boulevard.

DISCUSSION

A. J. SCOTT, M. D. (1501 South Grand Avenue, Los Angeles).—Doctor Tarr has presented his subject well. It takes an enthusiast to take a subject as this, and make it interesting and a stimulus to others to try. Doctor Abt has offered in this electric pump an easy as well as a simple method of milk expression. It would not be practical to use it in the home unless it could be rented from the physician, on account of the initial expense. It is a suitable piece of apparatus to use in any and all hospitals, but it must be used correctly to get results, and intelligently so as not to do damage, as is possible in the hands of an unskilled person. One nurse should have charge of the technique, and should do all the training of the nurses who use the machine. It is surprising what can be done in re-establishing or stimulating milk-flow. This machine convinces mothers, as well as doctors, that the new-born does not empty the breasts at feeding time.

It is not necessary to comment on the fact of the necessity of emptying the breasts to keep up the necessary milk supply. For the premature this machine is a great boon, for it does give him the so essential breast milk, and at the same time, the psychic effect on the mother is good.

We need among our obstetricians, as well as general men, more persistent and insistent teaching of mothers of the necessity of breast-feeding.

I have seen the result of this machine and have been well pleased, but my personal use of it has been very limited. The manual expression is used by me constantly, and I have had very good results.

ANGUS B. COWAN, M. D. (Fresno, Calif.).—The normal mammalian breast within certain definite limits will respond to the demands made upon it. The maximum output of milk is attained when the demand made upon the breast is greatest. A breast with an output of less than its maximum capacity may have the output increased when the demand is augmented. A breast with a capacity for larger output will automatically regulate the output to meet a diminished demand. An increased demand in itself will not cause an increased output in a breast functionally inefficient through other factors. Many such breasts exist.

The above seem to be established facts long known in the field of animal industry. Doctor Tarr's experiments give further proof of the wisdom of completely emptying the breast so that the maximum supply may be obtained. The contention that supplemental expression be adopted

Figure V.—Expressing milk from breast. With the thumb at upper margin of areola above and tip of index finger at areola below, a "together" movement is made which forces milk out of the ampoulae. Please notice that thumb and finger are properly placed and do not "hug" the nipple.

in all cases where the breast, after nursing has not been completely emptied, need not be conceded. Given a healthy vigorous infant and a breast that will functionally operate, it is held that sufficient stimulus to provoke a satisfactory output will be provided as the child grows older and his food demands become greater. This is well proven in Doctor Tarr's re-establishment cases. In the case of premature or delicate infants, where efforts at nursing are feeble, or in the case of mothers who give a previous history of having been unable to nurse their young, the point is well taken and such procedure held advisable.

The contention that supplemental expression should begin immediately after the birth of the baby needs additional proof before being attempted routinely. During the time of engorgement, when the breasts are swollen and painful, it would seem that utmost gentleness should be used, and further experiments are needed to prove whether it is better to begin stimulation at this time or await the period when the normal flow begins.

CLAIN F. GELSTON, M. D. (380 Post Street, San Francisco)—The great value of observations such as are presented by Doctor Tarr rests in the fact that a practical and easy method of stimulating the flow of breast milk is offered. The difficulties encountered in manual expression, in spite of the years of work of Sedgwick and his co-workers, have prevented a really conscientious effort on the part of physicians throughout the country to apply his teachings.

Proof is certainly no longer needed that it is essential that a breast be emptied for preservation of an appreciable flow of milk. The simple method, as devised by Doctor Abt, is a great step in popularizing a maneuver having the greatest of influence on preventive pediatrics.

ROBERT G. SHARP, M. D. (1000 Watts Building, San Diego, Calif.)—As a boy on a farm, I am sure that I earned more beatings for not "stripping" the family "Bossy" than for any other sin of omission. My father literally pounded this principle into me: "In order to maintain a good milk supply it is necessary to completely empty the udder at each and every milking." While in France with Sedgwick, he used to slap me on the shoulder and say: "Sharp, don't ever make the mistake of trying to stuff your mothers in order to make more milk. It only makes them fat and disgusted. Strip the breasts after each nursing, and you stimulate an increased milk supply." Again a principle was being pounded into me.

Now comes Abt with his electric breast pump and offers

the method de luxe for breast stripping. Dr. Tarr has clearly and forcefully set forth the uses and advantages of this breast pump. His contention that the premature and the new-born are practically never able to empty a full breast is undoubtedly correct. To these two types may also be added the weaklings and the lazy of whatever age. That we all recognize these facts and that we all agree with Tarr, is probably true. Is it not just as true that all of us are not at all times as diligent as we should be in our efforts to develop and maintain, and especially to re-establish an adequate supply of breast milk for the infant who cannot or will not develop his own? It is so often a useless struggle to induce the mother to strip her breasts after the infant has nursed, and so much easier to put the babe on a complementary formula which he likes, takes well, and upon which he commences an immediate gain, that we are too often prone to follow the path of least resistance. Along this line I wish to point out a real danger which we sometimes overlook, viz., too sweet a mixture. The best plan is to determine the sugar percentage in the mother's milk and then to keep the formula sweetness below this. The carbohydrate percentage may be added in a non-sweet form such as cream of wheat, cream of rice, rice flour or farina. For just as surely as the infant finds that he can get his milk sweeter or with less effort from the bottle, so will he follow the path of less resistance. He then becomes a lazy nurser.

Two very small points I would like to add to Tarr's excellent paper. First, that Dr. Abt's electric breast pump might well be placed in every pediatrician's office. Hardly a day passes but what some baby's milk supply should be analyzed. It goes without saying that the full breast should be completely emptied in the doctor's office by or under the supervision of a competent nurse. Second, that the pediatrician almost never gets the infant until the shortage of breast milk is apparent. Further in this connection, I would like to suggest that the time will undoubtedly come when the obstetrician will say to his patient, "I want you to decide upon the doctor that you are going to have for your baby, so that when baby arrives you can call him immediately." Then will we be able to stimulate breast-milk production to the best advantage.

DOCTOR TARR (closing)—This most excellent discussion of the subject convinces me that the vital matter of maternal nursing is not being completely left to the mother. It has been our experience that nursing mothers actually require most careful supervision. You cannot simply tell them to go home "and nurse their baby." The electric breast pump which Abt has given to us enables the attending physician to educate the mother, while she is still in her lying-in bed, along the proper lines of milk development. The warning sounded by Dr. Sharp is most timely and should be remembered whenever a formula is prepared for a nursing infant. Each day we listen to mothers who complain that since the baby was given a bottle, in addition to the breast, the breast has been slighted. I might add that the early giving of broth and well-seasoned soup stock to the nursing infant sometimes creates a disgust for food so bland as breast milk.

I wish to make my position absolutely clear regarding the matter of "expression." This procedure should never be relegated in favor of the pump Dr. Abt has devised or any other mechanical contrivance. The pump has now been modified in several respects, and hand-driven pumps are being made which sell for much less than the electrical pump. The rental plan may eventually be worked out, but the fact remains that each mother can take her two hands with her at all times, and when she has mastered the simple technique of "expression" she will have little need for a pump of any description. In the office of the pediatrician and in the maternity department of the hospital, the pump, in my opinion, can be used to best advantage. To insist that a mother, three or four days post-partum, should spend her energy in "expression after each nursing" does not appear logical to me. If a pump is not at hand, and if the services of a nurse are not to be had, the matter may safely be left until the mother is able to sit up comfortably.

Dr. Cowan is correct in his statement regarding my contention that breasts should be given added stimulation as soon as the baby is born. So far as I am aware, this

bold statement of mine has not appeared elsewhere, but my observations for the past several years and considerable experimental work have led me to the conclusion that the time to begin preparing the first meal for the baby is the day the mother becomes pregnant. We all encounter mothers to whom the act of nursing is decidedly repulsive. They cannot bear to have anything touch their nipples, and had their peculiar condition been studied and corrected during pregnancy, there would have been less to regret after the baby came. *There is but one way to insure the speedy solution of the infant-feeding problem. The family doctor delivers and directs the feeding of 85 per cent of all babies born. Let us detail him with a sane and practical plea that he teach all of his mothers the art of "expression" and when he has learned to talk breast milk to all of his mothers from the time they come for their first examination until the baby has a few teeth, then and only then may we hope, as pediatricians, to have time for a more careful study of some of the other preventive measures which must naturally occupy most of our attention. The family doctor should deliver babies and he should direct their feeding, but he should pay decidedly more attention to the matter of teaching preventive medicine to mothers than to the modification of cow's milk.* The electric breast pump can be used by him to wonderful advantage, and he will soon learn that breasts that are always emptied after a feeding will continue to function for a much longer time than those left quite to themselves. Dr. Scott has followed our work very carefully, and his conclusions agree with ours. The main thing is to *empty the breast*. In some instances the pump can scarcely be dispensed with, but "hand expression," routinely practiced, should be our constant teaching.

LENGTHENING THE QUADRICEPS TENDON FOR STIFF KNEE

By GEORGE J. MCCHESENEY, M. D., *San Francisco*

An operation entailing no risk to important structures, which presents no especial difficulties and will give a flexion range sufficient for all practical purposes in life, and which gets rid of an ugly tiring limp and a position of the limb which is always awkward and in the way, as in sitting in a street-car.

The operation requires three weeks in bed, after which the patient can be up and about on crutches, and would permit a return to light work within three months.

Pertinent discussion by Harold D. Barnard, Los Angeles; George Rothganger, Oakland; Leonard W. Ely, San Francisco.

THIS procedure, described first in the *Journal of Orthopedic Surgery* by Bennett in September, 1919, with two cases, and again in April, 1922, with six cases, has filled a long-felt want, particularly in industrial surgery. It does not seem to be as well known and popular as it should be, however, and hence, with an experience of five cases, I have ventured to come before you to plead its more frequent employment.

To briefly review the anatomy involved, we find the rectus femoris superficially and the crureus deeply in the midline, merging with the internal and external vasti, as they all come down to the patella. They unite so intimately in the lower third of the thigh, that pathological adhesions of one muscle cause restriction of motion in all, and that even, with adhesions in the upper third of the thigh, as occurred in two of my patients. The crureus is especially important, as it is in intimate contact with the bone in all its course. The question of the capsule naturally arises. My experience coincides with Bennett's. It can be disregarded, even the superior pouch. In all my patients there were soft, rustling tearings of cap-

sular adhesions, as the joint flexed only after sufficient work was done upon the tendon. In no case was there an effusion or pain in the joint afterwards, and the capsular adhesions did not re-form. As Bennett says, the knee-joint adhesions are entirely comparable to the ankle-joint adhesions following a long-standing equinus deformity due to calf muscle contractures. The real pathology is then above the joint. Again, anatomically speaking, there are no important nerves or vessels in the operation area.

We are all acquainted with the stiff knees following fractured femurs, with sepsis, either operative or due to the initial trauma, and with the joint uninvolved. Knees will resist motion, however, when sepsis has been absent, but when operative procedures have caused adhesions of the muscle to the bone, or when prolonged immobilization and disuse of the quadriceps have caused a simple resistant contracture without operation, quite analogous to the calf muscle contractures causing a foot-drop deformity. In the latter condition, achillotomy, or, better, a lengthening operation is done as a routine, and the same should be done to the quadriceps and completely supplant the blind and dangerous attempt to manipulate the knee in an attempt to regain motion. We have then three general pathologic conditions, causing stiff knee.

First. Adhesions of muscle to bone, following sepsis, usually an osteomyelitis, mild or severe, complicating fracture.

Second. Adhesions of muscle to bone or to muscle, following operation, but with no sepsis.

Third. Resistant contracture of the quadriceps with no adhesions, due to prolonged immobilization, as for joint disease.

THE OPERATION

A long median incision is made from the patella up the thigh to the middle third. The lateral margins of the rectus and the capsule of the joint are exposed. The rectus and the crureus beneath are separated from the vasti by deep, lateral incisions connected above. The whole is dissected free from the femur, and remains attached to the patella only, like a tongue. If with moderate force the knee then does not flex, it means that the vasti are still holding and the lateral incisions must be deepened. Bennett does not emphasize this point, but I have found it very important. In my worst cases the vasti were cut laterally a staggering amount before the joint flexed with the rustling tear of intracapsular adhesions. When the joint flexes, the tongue of rectus and crureus is sutured with kangaroo, silk, or chromic gut (I prefer the latter) to the adjacent vasti, and the usual closure of the superficial tissues is made. When much lateral cutting of the vasti has been done, there are rather marked depressions or sulci, which will give rise to dead spaces unless pressure padding is made with the dressing to obliterate them.

The knee is put up in plaster, in a position of 90 or 100 degrees flexion for three weeks, after which the anterior half is cut away and gentle passive motion is made for a week, with splint replaced at night. In the fifth week active motion is begun, and increased in amount as time elapses. The cast should be worn at night for eight weeks altogether.

It takes an indefinite time for complete extension to be regained. Bennett says a year for severe cases. I find the personal equation a marked factor, and with energetic stretching exercises, three to four months should be ample to regain power of extension to within 10 degrees of normal, actively, and completely normal, passively.

Recently one of the two first cases done by Bennett five years ago and reported by him in his original article, was examined at a meeting of the Industrial Section of the San Francisco County Medical Society. We found still lack of complete active extension by 10 degrees, but full passive extension and no disability. The man was scarcely conscious of the limitation and had practically perfect use of the limb.

Weight can be borne in five to six weeks, at first with crutches, but they should be discarded at about the eighth week.

My first case is the most interesting of the series, in that it was done for stiffness following old tuberculosis of the knee. The disease began in 1908, was treated conservatively by Doctor Harry Sherman and myself with plaster-splinting from 1910 to 1914. Weight-bearing was permitted in 1916, and in 1921 he presented himself with a painless joint permitting full extension and a flexion of 55 degrees. The patella was freely movable, the condyles not normally rounded, but there was no bony block to flexion, attempt at which caused pain in region of the patellar ligament. The boy was a machinist and was willing to undergo the operation and take the risk, in order to obtain better knee action. There had been no active disease for ten years, so the risk of lighting up the disease seemed fairly slight.

At operation in July, 1921, the quadriceps was lengthened, and flexion to 120 degrees then obtained with rupture of capsular adhesions, using only moderate force. Much greater force before lengthening the tendon accomplished nothing.

Subsequently, the course was uneventful. There was no flare-up, but, from fear of this, active motion was resumed very cautiously. He resumed work as a machinist six months after operation, and was seen three months later, when he had 90 to 95 degrees of flexion, and lacked 20 degrees of full extension. Two and a half years later I found the same range of flexion and 15 degrees restriction of full active extension. He had been working full time as a machinist at the Union Iron Works for two years.

This case is comparable to Bennett's seventh case, which was done for stiff knee following a septic arthritis. His case also had no flare-up. He lays down the opinion that the operation is permissible if all active joint disease has disappeared.

Case No. 2—B. T., aged 58, was my most unfavorable patient in age, condition of limb, and final result. A fracture of the upper third of the right femur received in September, 1920, was plated. Plate and splint were removed in six weeks. Naturally, angulation occurred. Was re-operated in March, 1921, for the angulation, and wore plaster and Thomas splints for five months thereafter. I saw him in April, 1922, when he had an active flexion power of 30 degrees, and full extension. Union in the fracture was solid, with marked outward angulation and a shortening of six inches. A month's physiotherapy and active bending exercises gained only a few degrees, and as he desired more flexion in his trade of plumber, operation was accepted, and done in July, 1922. Following the operation, there was considerable oozing, a trouble Bennett had in several of his cases; the healing was delayed, and with it active motion, as a result of which, when last seen by me in November, 1922, he had only 45 degrees of flexion or a gain of only 15 degrees. The mediocre result here was partly due to his lack of co-operation and disobeying orders, when active motion could have been practiced.

Case No. 3—D. C., aged 30. Left knee stiff after compound fracture middle third of femur, followed by several sequestrectomies and plaster splints for eight months. This happened three years before I operated in October, 1922, at which time he had a few degrees of motion, and a recent sinus in the fracture area following the exfoliation of a crumb of bone.

At operation, much of the vasti had to be cut away and there resulted a slight gape in the lower end of the incision, but healing was otherwise uneventful, motion regained, and a follow-up letter was answered a year later, in which he stated that his range of motion is almost normal, his strength in the limb and consequent comfort quite normal.

Case No. 4—G. D., aged 44. Compound fracture upper third left femur in November, 1920. Wired. Wire and sequestra removed, angulation ensued. Under treatment about one year.

Seen by me in December, 1922, and 30 degrees of motion found in joint, in spite of vigorous efforts on part of patient to gain more. He would sit on a table with block and tackle attached to foot leading to pulley behind, and cord coming forward on which he would pull, but with no result.

Operation done in December, 1922, and right angle flexion obtained, which, however, he had to fight to keep, but succeeded, as was shown at examination one year later.

Case No. 5—H. M., aged 22. Fracture of left femur, middle third, in November, 1921. Open reduction by writer same month, beef bone plate and screws applied. Union delayed, Wassermann two plus, and hence was in plaster spica five and a half months. Union eventually solid, good position, no suppuration, but flexion range of 30 degrees only. After six months of physiotherapy, more anti-luetic treatment, vigorous active exercise efforts, etc., the range of flexion was no greater, and operation done in December, 1922. Here again the vasti had to be cut freely before the joint flexed with rupture of a considerable amount of soft intracapsular adhesions, perhaps due to a luetic arthritis. There was no post-operative flare-up, however, but extension was recovered with some difficulty, as there was a chronic arthritis, probably luetic, with fat pads anteriorly for some months. He worked hard at the exercise treatment, and in March, 1923, had 115 degrees flexion, with three to five degrees loss of extension only.

SUMMARY

An operation entailing no risk to important structures, which presents no especial difficulties and will give a flexion range sufficient for all practical purposes in life, and which gets rid of an ugly tiring limp and a position of the limb which is always awkward and in the way, as in sitting in a street-car.

The operation requires three weeks in bed, after which the patient can be up and about on crutches, and would permit a return to light work within three months.

More radical cutting of the quadriceps would give flexion well beyond a right angle, but at the expense of much slower recovery of full extension, and hence is not advisable.

By the clinical findings at this operation, it is easily seen that resistance to obtaining a useful flexion where slight flexion power already exists is due almost exclusively to damage to the muscle and not to joint adhesions, hence manipulations of the joint are useless, in that force sufficient to stretch or tear the quadriceps is dangerous and should never be employed. This accounts for the almost universally poor or tragic results following attempted manipulations of the knee.

The subject of bony ankylosis of the knee is, of course, outside the scope of this article, but an

arthroplasty of the joint should never be attempted without careful consideration of the condition of the quadriceps muscle, as it can easily be seen that the Bennett operation may have to be done to obtain useful motion after the arthroplasty has been completed.

Furthermore, a chronic arthritis can develop from too prolonged and vigorous attempts at flexing the knee due to the constant strain and pull upon the patellar ligament. The pain is always felt in this region and not at the site of the adhesions or in the course of the quadriceps, consequently attention is wrongly directed to the joint as causing the restricted motion and not to the real cause above.

519 Fitzhugh Building.

DISCUSSION

HAROLD D. BARNARD, M. D. (2417 South Hope Street, Los Angeles, Calif.)—I do not believe that Dr. McChesney needs to be worried about the popularity of the operation of lengthening of the quadriceps tendon as advocated by Bennett. Obviously, because of the indications and contra-indications for the operative procedure, the occasion to use it presents itself in a very small percentage of patients, even in the practice of those who interest themselves purely in this type of work.

It is my opinion that the rationale and the practical applicability of this procedure is already well established—at least among that class of surgeons who are most often confronted by this particular type of problem. The personal equation associated with the after treatment of this procedure is extremely important. The after treatment is accompanied by a considerable amount of pain, and the reaction of the individual patient towards this pain is in direct proportion to the speed with which the maximum amount of function as an end-result is obtained.

I would also warn against the application of this procedure in arthritic patients, even of a very minor type. The end-results obtained in one of our cases in which there was a very moderate amount of arthritis were rather disappointing, and this failure to obtain a better result in this case was unquestionably due to the underlying arthritis, even though, as previously stated, it was of very light grade and was duly weighed and recognized, discussed and considered, prior to the adoption of the surgical procedure. Even the permanent loss of the final 10, or even 15 degrees, of full extension actively, is of very minor importance and of no particular consequence to the patient, and is not to be compared to the satisfaction to these cases of the additional arc of flexion obtained.

When applied to properly selected patients, this operation has come to stay.

GEORGE ROTHGANGER, M. D. (4501 San Pablo Avenue, Oakland)—It is a pleasure to read what Dr. McChesney has accomplished with the Bennett operation in those all too frequent cases of stiff knee attendant upon fractures of the femur. The success of his first case, while not due to fracture, is especially brilliant and must be a great satisfaction to him. The second case shows the limitations of the procedure, and the fourth and fifth the difficulty in holding the flexion secured by operation.

The causes of stiff knee should be held in mind by all of us treating fractures of the femur. The most common of these, in the reviewer's experience, is prolonged immobilization to secure union, the delay being usually due to lack of apposition of fragments and much less frequently to sepsis.

LEONARD W. ELY, M. D. (Stanford University Hospital, San Francisco)—Dr. McChesney is to be congratulated upon the results of his work upon a class of patients who ordinarily occasion a great deal of worry and trouble. It is always most annoying to be confronted with this stiffness of the knee after treating a fracture of the shaft of the femur, but personally I should hesitate to resort immediately to a Bennett operation until I had tried milder measures. However, I am ready to admit that these so-

called milder measures are not without their danger. I allude especially to passive motion. Sometimes, under ether, without too much force, the knee may be flexed a few degrees. Apparently, in some instances at least, these first few degrees are very important, for after motion has once been started thus, the patient himself can gradually extend his range. One other point—always be sure that the knee-joint has not been fractured at the same time as the shaft of the femur.

METASTATIC BONE CARCINOMA

By LYELL CARY KINNEY, M. D., San Diego

The clinical course of metastatic bone carcinoma is not consistent with the pathology.

Extensive metastasis with pathological fractures may occur before the primary growth is recognized.

Bone metastasis is not more painful or disabling than any other bone lesion of similar location.

Bone metastasis may be latent for months or years.

Bone metastasis may occur many years after surgery without local recurrence or enlargement of any lymphatic chain.

Symptoms and disability may fluctuate without relation to the progress of the disease.

DISCUSSION by W. O. Weiskotten, San Diego; W. L. Huggins, Los Angeles; Henry Snure, Los Angeles; W. Edward Chamberlain, San Francisco; Maynard C. Harding, San Diego.

THERE are many inconsistencies in the course of bone metastasis. The insidious onset, lack of disability, latent periods, and fluctuating symptoms make it hard for the physician to accept the diagnosis, and that diagnosis is often seriously questioned during the course of the disease. Also the roentgen examination reveals two widely different types of invasion that are confusing and at times difficult to differentiate from other lesions.

Probably the majority of slow-growing carcinomas give bone metastases. Schmorl estimates that 34 per cent of all carcinomas show gross metastatic bone lesions or microscopic deposits in the bone marrow. Kaufmann states that 70 per cent of carcinomas of the prostate and 50 per cent of carcinomas of the breast show bone lesions at autopsy. Bumpus has found 30 per cent of bone metastases in all cases of carcinoma of the prostate at the time the primary lesion was discovered. Jolly and Frankel report bone lesions secondary to practically all forms of carcinoma. The majority of metastases follow carcinoma of the prostate and breast, malignant adenoma of the thyroid, and hypernephroma. As Moore states, true carcinoma of the thyroid rarely metastasizes. Metastasis from rapidly growing visceral tumors is rarely found in bone, probably because of the short duration.

The usual location of metastases from the breast are: ribs, spine, femur, ilium, skull, and humerus. It is not uncommon to find all of these bones involved if the patient lives long enough. The lesion from the prostate reaches first the pelvis, lumbar vertebrae and femur, then, occasionally, the scapula and clavicle. A metastasis in the scapula is usually prostatic in origin.

The pathology of bone metastasis depends upon the primary lesion. If the original tumor is rapidly growing, with little stroma, the metastasis will be a rapidly destructive lesion and the bone will melt away before it. In the long bones the growth starts

in the marrow and expands in all directions, completely destroying the cortex or adjacent cancellous structure. In the vertebrae the destruction is an irregular, honeycomb absorption with irregular edges and leading to triangular compression. There is no new bone production; the process is purely destructive and the bone is replaced by translucent mass.

In contrast to this, if the original carcinoma is slow-growing or one having a large stroma content, the metastasis will show very little destruction and be accompanied by reactive sclerosis in the involved bone. The metastatic emboli may be too small to be demonstrated and the reactive inflammation throw down a chalky envelope that gives irregular increased density to the entire bone. Recklinghausen describes this type of metastasis as a carcinomatous osteitis. There is no formation of new bone with bone architecture, but calcium deposits surround minute cellular metastases to limit their growth. There is no cortical or periosteal thickening, but a diffuse irregular sclerosis. This osteoplastic type of bone metastasis is early and extensive in carcinoma of the prostate; the chalky appearance of the spine and sacrum being almost pathognomonic of prostate origin. However, it occurs in 14 per cent of breast metastasis and may come from any slow-growing carcinoma, whatever the origin.

The two types of metastasis may occur together in the same bone, or, as in case No. 2, there may be a destructive lesion in the humerus and an osteoplastic involvement of the pelvis. The osteoplastic lesion may break down as the disease progresses and the tumor outgrow the reactive osteitis, producing a massive translucent destruction. Case No. 7 presented a typical osteoplastic metastasis in the pelvis, and one year later showed a typical osteoclastic destruction of the wings of the ilia.

The diagnosis of bone metastasis may be very difficult. Primary round-cell sarcoma presents a picture identical with that of osteoclastic carcinoma. The sarcoma is more frequent in the epiphyses, occurring below the elbow and knee in young patients, while the bone carcinoma is situated near the nutrient canal above the elbow and knee, and usually has a demonstrable primary lesion.

Paget's disease very closely simulates metastatic carcinoma from the prostate. Both may show the same chalky, white density of the spine and sacrum. The differentiation is made by search for primary lesion in the prostate or the typical bone picture of osteitis deformans in the extremities or skull. Paget's disease is a true proliferating osteitis; the architecture is destroyed, but again laid down in long longitudinal striae with proliferating periosteal bone and thickening of the cortex. Carcinoma does not give new architecture or periosteal proliferation. Carmen points out the difference in the lumbar vertebrae which are widened and flattened in Paget's disease, but retain their outline in osteoplastic carcinoma. Paget's disease is never localized to the pelvis, and the pathognomonic signs in the skull are usually present at the first examination.

Hypertrophic spondylitis should give no difficulty in diagnosis, for the thinning of the disks and the bony bridging form a sharp contrast to carcinoma which is limited to the bodies of the vertebrae.

Syphilis of the pelvis shows dense uniform sclerosis with cortical widening and periosteal thickening that differentiate it from the irregular granular density of osteoplastic carcinoma.

The clinical course of bone metastasis bears no relation to the severity or progress of the disease. There are usually rheumatic pains and, if the spine is involved, radiating pains. Frequently spontaneous fracture is the first evidence of metastasis. There may be extensive bone lesions before the primary tumor is recognized.

Case No. 5 showed destruction of the lamina of the twelfth dorsal vertebra, and Case No. 6 presented complete destruction of the body of the fourth lumbar vertebra before the patients knew they had a breast tumor. Likewise, there may be an extensive involvement of the entire bony pelvis, or even a fracture of the neck of the femur, with trivial urinary symptoms arising from a primary lesion in a small prostate.

The pain is usually increased on motion, and in carcinoma of the spine it is not relieved by the recumbent posture; but bone metastasis may not be more painful or disabling than any other bone lesion of similar location and extent. Occasionally there is no pain preceding spontaneous fracture.

Bone metastasis is at times latent for months or years. Case No. 2 presented the worm-eaten structure and triangular compression of the twelfth dorsal vertebra secondary to breast carcinoma and had localized pain not relieved by position. After two years the patient is sitting up and there is very little change in the appearance of the vertebra. Case No. 8 enjoyed a symptomless interval for eight years after the amputation of a breast, and now shows a typical carcinoma in the head of the adjacent humerus. Case No. 1 developed a spontaneous fracture in a painless metastasis of the humerus following a carcinoma of the jaw thirty years previously.

Bone metastasis may occur without enlargement of the lymphatics draining the primary tumor. Case No. 4 was followed through a metastatic carcinoma after a breast amputation. There were no demonstrable glands at the time of surgery. Twenty months later a metastasis appeared in the twelfth dorsal vertebra and the wing of the left ilium, later involving the pelvis, both femora and humeri, ribs, cervical spine, and skull. At no time were there any palpable enlarged glands or local recurrence.

A most striking feature is the fluctuation of symptoms independent of the progress of the disease. The patient just mentioned had intervals when she could turn with comfort and use her limbs, in spite of the progressing destruction of pelvis, dorsal and cervical vertebrae. Hollis Potter reports a woman patient who walked into his office two years after the discovery of a spinal metastasis. Case No. 7 was examined a year ago at the hospital, showing an osteoplastic metastasis in the pelvis, sacrum and lumbar vertebrae. He was helpless, bedridden, and suffering intensely. Last week he walked into the office, claiming that he was free from pain and desiring to check the diagnosis. The examination showed complete destruction of the wings of the ilia and extension of the metastasis.

In conclusion, the clinical course of metastatic bone carcinoma is not consistent with the pathology:

1. Extensive metastasis with pathological fractures may occur before the primary growth is recognized.
2. Bone metastasis is not more painful or disabling than any other bone lesion of similar location.
3. Bone metastasis may be latent for months or years.
4. Bone metastasis may occur many years after surgery, without local recurrence or enlargement of any lymphatic chain.
5. Symptoms and disability may fluctuate without relation to the progress of the disease.

1831 Fourth Street.

DISCUSSION

W. O. WEISKOTTEN, M. D. (First National Bank Building, San Diego)—We have been accustomed to look on any form of carcinoma as a progressive disease which does not remain quiescent, but which has a tendency to destroy life within a few years. Dr. Kinney's statement that certain forms of metastatic bone malignancy may remain inactive for years and in some instances actually show an improvement in the clinical symptoms is interesting and explains the cases which have been given a roentgen diagnosis of metastatic carcinoma and later improved to a degree which made the original diagnosis questionable.

In a general way we may assume that practically all bone carcinoma in the female has its primary focus in the breast, because pelvic carcinoma in the female rarely metastasizes. In the male the primary lesion in practically all patients is in the prostate or tongue. Theoretically, bone malignancy should be easy to recognize if one considers the cardinal points in differentiation of bone tumors, but, as a matter of fact, atypical forms of bone metastases in their early stages make a final and conclusive roentgen diagnosis oftentimes difficult. The very patients who two years after diagnosis walk into the laboratory for a check-up, make us wonder whether the original diagnosis was correct.

W. L. HUGGINS, M. D. (Pacific Mutual Building, Los Angeles)—Dr. Kinney's paper is a timely contribution to the study of the cancer problem. The percentages quoted are somewhat of a surprise, as I have seen very few cases of bone metastasis. This moment I recall two, following carcinoma of the breast. One occurring in the spine and the other in the tibia, both within a year following radical operation of the breast and without local recurrence in either case. Undoubtedly, there are more of these metastatic cases than the average surgeon realizes, and suspicious cases should have a careful study.

HENRY SNURE, M. D. (1501 South Figueroa Street, Los Angeles)—I was much interested in Dr. Kinney's report of a carcinoma recurrence of the jaw after an interval of thirty years. Recently, in looking up the literature on recurrence, I found only one report of a recurrence after thirty years; this was a case of breast carcinoma. Two other instances of late carcinoma recurrence were cited, one of the rectum after twenty-one years, and one of the tongue after eighteen years.

Dr. Kinney's opening remarks regarding difficulty of differentiation of the types of carcinoma suggest to me that if the roentgen ray societies would take up the study of carcinoma along the lines of the Committee on Registry of Bone Sarcoma of the American College of Surgeons in the cases of bone sarcoma, we would soon be able to improve both our diagnosis and prognosis of these trying cases. Close co-operation with our pathologist will be our greatest aid.

W. EDWARD CHAMBERLAIN, M. D. (Stanford University Hospital, San Francisco)—I was much interested in Dr. Kinney's statement concerning Paget's disease, that it would not be found in the pelvis without evidence of involvement elsewhere in the skeleton. Doubtless, that would be true if tissue examinations were possible. But

we have had the experience, in more than one patient, of making a careful roentgen examination of the entire skeleton and finding evidence of Paget's disease in the pelvis only.

Kinney has emphasized the remarkable inconsistency between the progress of the growth in metastatic bone carcinoma and the patient's symptoms. This has an important therapeutic application. We must not be too quick to ascribe a lessening of symptoms to a certain therapeutic procedure. A certain cancer vaccine, now known to be valueless, was enthusiastically sponsored by careful and honest surgeons some years ago. Much misplaced enthusiasm resulted from coincidental pain remissions in some of the spine metastases which are to follow breast cancer.

MAYNARD C. HARDING, M. D. (Electric Building, San Diego)—Having been associated with Dr. Kinney in several of the cases which form the basis of his excellent paper, I can bear witness to the very widespread and often symptomless metastases which his systematic roentgenography revealed. I have been especially impressed with the number of iliac lesions.

We all speak confidently of metastases occurring after five to twenty years' freedom from the original carcinoma. In view of the known progressive course of the disease, and of its unknown causation, we might well let ourselves think of such metastases as being possibly fresh attacks. Such a conception will at least fit in better with the newer theories about cancer.

Leisure—For What?—In a thoughtful and thought-provoking discussion of this always timely subject, George W. Alger (Atlantic) says many things of use to physicians in their daily lives and practice: "The main contribution of the automobile to the happiness of a growing leisure class, says the author, 'is that it furnishes a new way of transforming an otherwise unbearable leisure into a mode of motion, with gasoline performing the function of a soothing syrup for grown-up children. . . . When we learn to classify men as inferior or superior by what they do with their leisure, we shall attain, among other results, a new angle upon race prejudice and perhaps find a new solvent for the heretofore insoluble. . . . A civilization that creates a leisure which it cannot rationally use may well be in greater danger of destruction than one that has no leisure at all. A civilization that bores its beneficiaries is perhaps even worse than one that overworks its slaves. . . . The great problem before us today is to create a civilization that does not degenerate under leisure. This can be done only by setting in operation forces making for a culture that recognizes, as no civilization since the fall of Rome has been required to do, that leisure is and must be a means and not an end; that its true value is measured by what we do with it—by whether it lifts us or lowers us in the great world of intangibles, the world not of material, but of spiritual values.'"

Pathetic—Dr. C. Hilton Rice, Jr. (Scientific Monthly), thus characterizes the spoiled child: "To change the feeding habits of the child requires the changing of the parents' habits of dealing with their child. For a child that is allowed to eat anything that it likes, and at any time it likes, is almost invariably a spoiled child, and the spoiled child is a difficult case to deal with. If a child gets off wrong, if he acquires dislikes for essential foods, these habits are likely to become fixed and permanent so that his whole future is affected. If ever there is a time when the firm hand of discipline needs to be used in the training of a child it is in this early irresponsible age when the child is tasting his adventurous way through the lists of foods that make up the human diet. . . . The longer a child has been on a one-sided diet, the stronger become his food prejudices and the more difficult it is to hold him to a balanced ration. It seems as though his tissues and organs become specialized, as it were, to certain kinds of foods, and always there is the old subconscious pull of habit that drags him back to his old ways of eating. That is why it is so difficult to feed the older child whose habits of diet have become fixed."

THE CHINESE HERBALIST AND THE MEDICAL PRACTICE ACT

By C. B. PINKHAM, M. D.,

Secretary California Board of Medical Examiners

As far back as runneth the mind of man has the Chinese "herb doctor" been a problem in California. We do not believe that there is a remote possibility of passing any legislation that either will effectively stop these Chinese herbalists from operating or put an end to their advertising, unless there be an unbelievable change of attitude in public opinion, an awakening of the lower courts and enforcement officers in many localities to a keener sense of civic responsibility in law administration, and more manifest co-operation evidenced by a change of policy on the part of some of our papers as to the type of advertising accepted for publication.

WE HAVE read with growing interest the article on page 330 of the March issue of CALIFORNIA AND WESTERN MEDICINE, where, in commenting on the Chinese herbalist situation in California, the Board of Medical Examiners is invited to supply some facts which may explain why the Chinese herbalists are permitted to advertise as they do in the daily papers. It is self-evident that the question should be directed to the advertising manager of each paper, for through him all advertising contracts are executed. A newspaper will not print any advertisement unless a contract had been signed and the "copy" had been submitted to the advertising department for publication.

As an example of the difficulties encountered in attempting to stop illegal advertising on the part of Chinese herbalists, we will relate a recent instance. Not long since the attention of the Board of Medical Examiners was called to such advertisements as "Dr. Chow," "Dr. Woo," "Dr. Lau Yit Cho," etc., and we thereupon undertook to exact compliance with the law by charging a specific herbalist with illegal use of the prefix "Dr." At the preliminary trial a charge of using the prefix "Dr." cannot be sustained unless the *advertising solicitor* will identify the defendant Chinese as the one who signed the advertising contract, frequently an impossibility, as the Chinese attendants (both translator and doctor) in the herbalist's office change frequently, or at least they change their names. Seldom will an herbalist give the same name when arrested on a second charge of violation of the law. Without identification of the defendant Chinese as the one who signed the advertising contract, the prosecution collapses.

An advertisement of a Chinese herbalist recently appeared in at least one of the San Francisco papers, reading: "If you are sick, come to us and have us give you a *scientific diagnosis* that will tell you absolutely the true condition of your whole system." This advertisement contradicts the usual court defense of the Chinese herbalists who, when charged with violation of the Medical Act, testifies that he did not "diagnose" but acted in the capacity of a storekeeper selling rice, tea, and sometimes herbs. At the preliminary hearing of the Chinese herbalist, whose "firm" used the above advertisement, the investigator for the Board of Medical Examiners, who, by the way, fully understands Chinese, testified that he understood the conversation carried on between the interpreter and the Chinese (doctor) herbalist,

who asked what pain the patient had, whether heart, back, or stomach, that the interpreter asked a fee of \$12, was paid \$5, and when asked for a receipt, gave the witness a small piece of card with a number on it, telling him to return. On the second visit the Chinese (doctor) herbalist placed the patient's hands on a pillow, felt the pulse, and said "She got a bad cold."

The advertisement mentioning the "scientific diagnosis" quoted above *was not admitted in evidence at the trial because the advertising solicitor testified he could not identify the defendant Chinese as the individual who gave him the advertisement.* This case is now under consideration by a police court magistrate as to whether the evidence submitted is sufficient to hold the defendant Chinese for trial.

The Better Business Bureau, which stands for honesty in advertising, should interest themselves in advertising of this nature, particularly when the statement is made that a "scientific diagnosis" will be given. Our investigators report that the "scientific diagnosis" made by the average Chinese herbalist consists in feeling the patient's pulse, looking at his tongue, and asking some questions as to his condition. It is then customary to brew some concoction for the patient to drink, some often given him to take away, and he is told that treatment will cost \$10 to \$12 per week, payable in advance.

CALIFORNIA AND WESTERN MEDICINE, May, 1925, page 617, in an editorial, "What About These Law Violators," quotes the above-mentioned advertisement, reading: "Come and have us give you a scientific diagnosis that will tell you absolutely the true condition of your whole system" (Chan & Kwong—Chan & Chan), with the comment, "If this isn't flagrant disregard for law, what is it? Why are these law violators not punished?" As a result of the activities of the Board of Medical Examiners this illegal advertising was recently corrected. The records of the Board of Medical Examiners show we have been most active in presenting to the courts throughout this state what we consider as irrefutable evidence of violation of the Medical Act on the part of many Chinese herbalists.

A certain Oakland Chinese herbalist, referred to as "Dr." in his newspaper advertising, when recently brought to trial on a charge of violating the Medical Practice Act, *displayed letters patent from Washington, showing he has been issued a patent on his name, thereby claiming legal authority to use the prefix "Dr."* despite the prohibition of such prefix by the California law. Legally this had no bearing on the case and properly should not have been permitted presentation in court.

The system under which preliminary hearings are held differs in various localities. The city charters of Oakland and Los Angeles permit a trial *by jury* in the police court, whereas in the majority of California cities and towns the preliminary hearing of one charged with law violation is held either before a justice of the peace (if the community be small) or before a police judge in the larger cities, such as San Francisco. After the evidence has been submitted the judge takes the matter under advisement, dismisses or holds the defendant for trial.

Considerable time invariably elapses between the

filing of the complaint and the first or "preliminary" hearing of the charges before the justice of the peace or police judge. This delay is often due to the congested condition of the court calendar; however, not infrequently the hearing is put over time and again at the request of the attorney for the defendant, who hopes as a result of long delay that the witnesses for the prosecution will have disappeared. In the instance of a trial (not an herbalist) recently completed in the Oakland Police Court, our Investigation Department reported that practically two and one-half years had elapsed between the time of arrest and the time of trial of said violator. During this period of delay seventeen postponements were reported. After the defendant has been held for trial in the Superior Court, again ensues a more or less extended delay, frequently occasioned by the attorneys for the defendant. The longer the trial is delayed the greater are the possibilities that witnesses for the prosecution will have disappeared.

The records show a surprising number of dismissals in the lower courts. Reference to the 1921 annual report of the Board of Medical Examiners (page 35) shows that during that year fifty-four Chinese herbalists were charged with violation of the Medical Practice Act in Northern California and twenty were dismissed (about 38 per cent); while of fourteen arrested in Southern California, only one was dismissed.

The legal report of the board is printed in each issue of the directory, which makes possible a complete check on all phases of our enforcement work.

An article, "The Problems of Enforcement," page 13 of the 1920 annual report of the Board of Medical Examiners, reprinted on page 231 of the 1921 directory, explains some of our difficulties.

Assembly Bill 440, introduced by Mr. Ed. Smith, which occasioned so much comment during the 1925 legislative session, had possibilities in effecting some modification of existing conditions and it has been suggested that a satisfactory conference bill might have been drawn, but we can foresee no legislation that will "close up" the Chinese herbalist.

Perchance a few Chinese herbalist cases reported by our Legal and Investigation Department may prove of interest.

A certain Chinese herbalist not far from San Francisco was reported by our former special agent to have passed him "protection money" in plain sight of a police officer, who promptly arrested the Chinese. The case was dismissed, *the judge holding that inasmuch as said investigator was not a sworn officer of the law, the giving of money for protection did not constitute bribery, nor was it an offense.* The law was thereafter amended so that special agents of the board are now sworn officers of the law.

A Chinese herbalist who gained considerable notoriety during the past legislative session was arrested January 5, 1925, in a neighboring city. The case was continued until May 8, 1925, when the case was put over to September 15, 1925. Commenting on the situation, our special agent on May 9, 1925, reported that list of witnesses was sub-

mitted to the district attorney on February 28, 1925, and return made May 7 (the day before trial) showed only one of the four witnesses could be found; that this information was conveyed to the representative of the board "twenty minutes before the case was called . . . the jury had been summoned . . . although the witnesses were not obtainable. . . ."

Some time ago our investigator reported the arrest of a Chinese herbalist in a northern county. A search of his premises netted abortion instruments, admittedly his, and he confessed practicing medicine. Conviction.

A certain well-known Chinese herbalist in a Northern California city, prominently involved in the recent legislative controversy, had at his office door for many years an ornate brass sign reading, "Physician and Surgeon—Eye, Ear, Nose and Throat," until after many attempts he was finally convicted by the legal department of the Board of Medical Examiners. This conviction was sustained by the higher courts, and he then paid a fine of \$500 and spent four months in the county jail.

It is reported that this wily Celestial for years has retained each new district attorney as his *personal* attorney. Newspaper reports relate he "has been fined heavily in the federal courts and justice court for selling drugs illegally." He has also been charged with performing illegal operations. Prosecution of this individual has been surrounded by unbelievable difficulties.

If space permitted we could relate many other instances to show that the Chinese herbalist is not the asserted innocent storekeeper selling only tea, rice, and occasionally some herbs.

An illuminating article narrating the operation of the Chinese herbalist was published in the *Dear-born Independent* of August 9, 1924. Therein is stated that the Chinese medical system was founded in 1578 and has not been changed since. "For 346 years Chinese 'doctors' in China and abroad have followed this book (Pen T'Sao) without changing their drugs, their compounds of those drugs, or their methods of medication."

"Diseases in China," by Jeffereys and Maxwell, relates "To become a physician a Chinese states to his friends and neighbors 'I am a physician.' This is the limit of required preparation. The Chinese doctor's diploma is a more or less handsome sign-board, which announces his determination to the neighborhood."

The *China Medical Journal* 38:679, August, 1924, recites that Chinese physicians are mostly purveyors of superstition, excepting a small group of those trained abroad or at home in modern medical science. Ancient customs embrace or condemn views quite opposite to Occidental standards. Most native Chinese physicians rely on few remedies which may be of value, but the composition is a closely guarded secret.

EDITORIALS

THE FIFTY-FOURTH ANNUAL SESSION, CALIFORNIA MEDICAL ASSOCIATION

We had hoped to publish in this issue something about the session of the California Medical Association held in Yosemite, May 18 to 21. This we are unable to do because we *must go to press on schedule* and were not able to secure enough advance material to make the June issue interesting about convention matters. The July issue will carry what we can get of news, presidential, section chairmen, and other general addresses. Also, we hope, the proceedings of the House of Delegates and Council.

THE CHINESE HERBALISTS AND THE MEDICAL PRACTICE ACT

Particular attention is invited to the article under the above title by C. B. Pinkham, executive officer, California Board of Medical Examiners, published on page 737 of this issue. Doctor Pinkham tells a disheartening and discouraging story of a matter that is a disgrace to California. We get a peep into conditions that read like tales of other bootleggers; some "slants" that indicate with clarity what mercenaries will do for money and how they can and apparently do reach far into our social structure for support that they must have to successfully carry on their nefarious practices *in violation of law*, and also at the expense of public health and welfare.

Why is it that these bootleggers and traffickers in health can, and do, not only violate the law openly and flagrantly, but boast of it and invite other victims in paid space in some of our newspapers daily? Doctor Pinkham indicates an answer and how it works. What a spectacle it is that a "*Doctor Yun*," or some such name, may secure "letters patent" from the patent office of our national government and then introduce this legal document in defense of his violation of the laws of California designed to protect the health of our citizens!

The bureau of the patent office at Washington is under Secretary Hoover. We would like to see this practice put up to him, having confidence that, if in his power, it would be discontinued. The practice of federal bureaus of nullifying and overriding state laws by executive action of some political clerk or other creature is not as popular in Washington as it once was, and we have every confidence that in so far as lies in his power our fellow Californian, Secretary Hoover, will not encourage the creation of "doctors" by "letters patent."

Doctor Pinkham's illuminating comment upon the practices of some of our lower courts explains much. Such publicity ought to be followed up, giving names and dates. CALIFORNIA AND WESTERN MEDICINE will be glad to publish enough of such facts from month to month to eventually arouse the interest of some worthwhile civil organization genuinely concerned with practical problems of public welfare. Doctor Pinkham, we regret to note, appears to feel that in our various references to "herbalists" and other unlicensed persons who practice medicine in California in violation of law,

but nevertheless with an apparent cast-iron immunity, we are criticizing the Board of Medical Examiners. Nothing is further from our intention. All the members of the board are educated doctors of medicine and most of them members and officers of the California Medical Association, and therefore part owners of CALIFORNIA AND WESTERN MEDICINE. We are aware of some of their difficulties, but we do invite them to use CALIFORNIA AND WESTERN MEDICINE more fully and freely, as has been done in the present instance, in keeping their problems before our physicians, other health agencies, and through them, the general public. Such publicity reaches far and it will reach farther as time goes on. It is the only available method by which physicians can widely show their sound position and active interest in this important plan of public health and even decency.

No, Doctor Pinkham, we are not after you or our other friends who are members of your board. All doctors pay, and most of them willingly, a special tax to carry on your work. If a light step upon your toes produces such illuminating discussions of an important subject as your present article, and such can be obtained in no other way, other bruises may prove salutary.

We want to work with you in a common cause—not against you; but most important, we want to work.

HOW PHYSICIANS' SERVICES ARE MADE AVAILABLE TO THE PUBLIC

Once upon a time a young lady made herself and her surroundings as attractive as she knew how or could afford and then waited for some young man to become interested in her. Most young physicians obtain their start in practice by an analogous method. It is said that modern young women are adopting more progressive tactics, and there is an element of considerable magnitude developing among physicians by which they also will become more active in getting started in their life work. Some of these methods will be considered in subsequent articles, but first it is well to look into the old-fashioned way a little more closely.

The vast majority of people still consider it their personal privilege to select their life partner, their physician, and their dog. Many and divers attempts have been and are now being made to restrict personal liberty upon all three points. If any of them makes progress enough to arouse general interest, there will be a reaction that will make prohibition enforcement look like a tea party.

Not only do most people believe that their selection and method of compensating their physician is a private and personal matter, but the vast majority of physicians agree with them. While this method often means lean years for the young physician, it nevertheless is part of the charm of the profession, and it is an important element in the romance of medicine and the sanctity of the relations that surround and guard the patients.

Young physicians always have, and probably always will, object to the sacrifices most of them make during the hard, lean years while they are making personal friends and converting them into

professional friends and patients when medical services are required. Most older physicians look back upon these years without regret and with a realization of all they meant in self-discipline, self-analysis, increased study, hospital experience, and the development of the capacity for human understanding and sympathy that proves so necessary in their work.

In other days, when part of the medical student's training consisted in an apprentice service with an older physician, many of the first and difficult lessons were learned by precept and example. Nowadays the student spends his days in laboratories and hospitals, where every activity is part of a well-organized whole; where patients are often "cases," and problems are red ink and black-ink notations on "case records." The modern method undoubtedly produces a more scientific physician and one more competent from that standpoint. But modern education leaves him with more serious problems than had the young graduate of a few years ago. He is trained to rely upon laboratories, x-ray, and many other expensive and complicated devices for diagnosis and treatment. He finds it difficult to practice medicine without them, and he cannot afford to buy them. Even many of the hospitals, particularly in smaller communities, are without these accessories, and the young graduate has a hard time readjusting his methods to meet the actual conditions of life.

The greatest problem of the young physician is to fit himself into the social, economic life of the community, and particularly to fit his professional personality into things *as they are*. In this, the art and personality of medicine, the modern young physician has a much harder time than his colleague of a few years ago who learned these lessons from his preceptor while serving his apprenticeship.

MEDICAL ORGANIZATIONS ASSUME LEADERSHIP

County and state medical associations here and there are establishing clinics and otherwise taking steps to put medical leadership actually into effect. We have been saying this should be done for about as long as medicine has been a profession. The doing of it is another matter, but if the sporadic attempts are well planned and well supported, there is a chance that educated physicians might again take a more influential place in the practice of personal and public health.

In some places county societies have started and are operating their own clinics for the care of the economically and socially insolvent. In other places they have established co-operative plans with other health-promoting organizations, whereby the medical society fixes policies and furnishes the physicians, while the co-operating public health board or other organization supplies the funds and the clerical and technical assistants who operate under the supervision of the medical society. In Illinois, for example, according to Doctor H. M. Camp, secretary of the State Association (Bulletin A. M. A., April, 1925), this movement is attaining interesting proportions.

What medical society will be the next one in line?

Medicine in the Public Press

The "Fast Way to Health"—"Dr. Frank McCoy, 'noted dietitian and diagnostician' of Los Angeles, was brought to San Francisco by the San Francisco Bulletin," says that paper, "to give a series of lectures for its readers, free, on 'how to reduce' and also how to travel the 'fast way to health' on the proper combination of foods and correct physical culture exercises. The lectures began Friday, May 15, 'on the ART of reducing.' The lectures were much advertised as open to everyone—both men and women—without any 'charge whatever.' Come and bring your friends," advise the headlines.

On the illustrated half-page, telling about what this "noted doctor" can do, we note of entertaining value to physicians that "Dr. McCoy says that *no matter what the original cause of the goiter may be, the cure is always possible through the use of the fruit fast*. This treatment removes the thickened material from the blood, and the circulation carries it off. The thyroid decreases in size and sometimes disappears entirely, but if the size does not entirely diminish, the load is taken off the heart and the circulation is improved." There is plenty more just as entertaining and (?) reliable.

The Ideal of Child Health—An editorial in the Woman's Home Companion, under this headline, says in part that: "There is a doctor in New York who gets a fee of \$15,000 a year just for guarding the health of a millionaire's children. He calls twice a week, plans their diet and their exercise, and catches any small ailment before it can become serious. If the children fall ill, he treats them. The idea, however, is to keep them well. This is worth \$15,000 a year to the millionaire, and it would be worth as much to every parent. But few can afford even a hundredth part of that sum for a physician's care. *For a small fraction of it—or \$1.50 a year—the readers of this paper (Woman's Home Companion) get once a month the advice of experts on child health.*"

The italics are ours. Such cheap medical service is entitled to have italics.

Modern-day alienists are creating the impression that to be insane is not really a reflection upon one's intelligence.—Birmingham Age-Herald.

"Wrong-Headed Zealots"—Under this heading the New York Herald-Tribune says, editorially: "The foes of medicine calling themselves the Citizens' Medical Reference Bureau touch the extreme of nonsense in objecting to the proposed statue of the dog Balto because he made his glorious trip to Nome on a nefarious errand, carrying antitoxin to diphtheria sufferers. They seem to think that Balto is an eminent bacteriologist. The protest is only a grotesque play in the campaign to harass physicians in their winning fight against a deadly disease."

"The wrong-headed bureau seizes this occasion to spread the impression that diphtheria antitoxin is a failure. It practically represents Dr. William H. Park, director of the city's laboratories, as having admitted as much. Dr. Park, of course, has said no such thing. No physician in the country is more convinced of the wonderfully efficient results of antitoxin and of the value of immunization by means of toxin injections."

"Use is made of the statistics of Willard Parker Hospital to prove a high rate of mortality from diphtheria. The anti-medical bureau stresses the 35 per cent of mortality among children under 3 years old at the hospital from 1919 to 1923. It omits to mention that in the years before antitoxin was administered the rate was 80 per cent. Nor does it explain that a great many of the cases are received by the hospital in an advanced stage, when antitoxin is all but powerless. Prompt treatment is essential."

"Before antitoxin came into use, the death rate from diphtheria in New York City was 150 per 100,000 of population. Thereafter, in 1898, it was reduced to 54. With some fluctuations, it was reduced in succeeding years to 22 in 1919, when the immunizing vaccine became

available. It declined in 1923 to the low mark of 9 per 100,000. The life-saving potency of antitoxin applied in time and the protecting virtue of the preventive injection are facts abundantly proved. Let no mother or father for an instant credit the assertion of persons who hate physicians and all their works that the modern treatment of diphtheria is of questionable value. It is indeed one of the great triumphs of medicine. Were every parent instructed, one of the most dreaded diseases of childhood might ultimately be subdued.

"It is sorry business for any organization, however sincere, by deceptive use of figures and the garbling of statements of a public health official to try to cast doubt where none exists on the efficacy of antitoxin and of immunization against diphtheria."

The Ubiquitous "Sunday Supplement"—Doctor, was your sense of humor or your enjoyment of the ridiculous sufficiently elastic to permit you to read in a recent Sunday Supplement how cockroaches act as "Carriers to the Carrier" of the "cancer germ"? Some article that! and as for the illustrations, Oh boy! The trouble with fake stuff of this character is that some people not officially rated as especially "moronic" believe it, as is attested by letters of inquiry. The chief reason for this alleged scientific article is to promote the use of "roach powder" as the "only way" to get rid of these "bugs that bring us cancer."

"Baby Congress and Health Exposition" Under Medical Auspices—Newspapers have given much space to a national baby congress and health exposition sponsored by the Illinois Medical Association. It is said that "the congress has the support of the American Medical Association and the Chicago Medical Society, whose officers, with those of the Illinois State Medical Society, are in supervision."

Some 14,000 babies and many older children and adults attended the exposition, which was "in no sense a beauty show, but strictly a health show. All things related to health found a place in the exhibits, and no exhibits of disease found a place on the exhibition floor."

Provisions were made for a complete physical examination of all persons by a staff of 765 members of the Illinois Medical Society.

This looks, at this distance, very much like medical leadership in action.

Public Schools for Babies—The Metropolitan press of an Eastern city recently gave prominence to a movement—or a gesture—to provide public schools for babies—"nursery schools." It seems that some of the uplift organizations, after repeated "conferences" and much "research" have arrived at the conclusion that the "only way" to properly prepare oncoming generations to meet adequately the rough and tumble of life is to take the babies away from their "incompetent mothers" and "unsanitary and unhealthy home environment" generally, and place them in specially designed public schools. In fact, the "Infant School Society" already have several of these schools in operation. They are apparently modeled closely after those that have been featured as part of the health activities of socialistic centers in Europe.

Publicity As a Health Asset—"Experience has shown," says the Ohio Health News, "that the wider the spread of publicity, the less the spread of disease in any neighborhood epidemic; that the more concealment is tried, the longer the disease lingers; that other means of communication exist whereby news, especially bad news, travels rapidly, and generally badly distorted; that plain facts about local health conditions should always be given the public."

Spoofing the Press—Medical editors, who have an opportunity to see all they care to see of the "News Release" about health and welfare, are at first amazed and then become thoroughly disgusted with the stupid tommyrot that government bureaus and other propagandizing agencies and persons have the temerity to try to get pub-

lished as "news" or as "scientific data." For example, the Census Bureau gives us the interesting and useful information that in America some 187,000 babies died last year between birth and one year of age, and that over half of these died during the first month of life. Another government bureau, after what was no doubt an expensive "survey," then takes the Census Bureau figures and their own "findings" and turns them loose, ready to print as "news." This alleged news contains statements that are about as much news as is a statement that cough is a symptom of tuberculosis. Some of the statements that they apparently consider news are:

"A thorough knowledge of the causes of infant mortality is the first step toward their complete control." What an erudite statement!

"The pathological causes of infant deaths must be reported on death certificates by the physicians in attendance. But the analysis of infant mortality, if it is to be thorough, must be carried beyond the pathological cause to antecedent and predisposing causes and casual factors." (Italics ours.)

Among the causes of infant mortality which this bureau feeds out as "news" are:

"Seasonal conditions influenced the mortality rates."

"Factors relating to the physical condition of the mother also influenced the mortality rate."

"First-born children had a slightly higher mortality than second-born."

"The mortality rate was highest for infants born within a short interval (within approximately one year) after preceding births."

"Mortality from all causes was much higher among twins and triplets than among other babies."

"Mortality among the exclusively artificially fed babies averaged between three and four times that among the exclusively breast-fed."

"Housing congestion, employment of the mother away from home, and low earnings on the part of the father, were other very important factors influencing the infant death rate."

Facts, yes, but already so well and widely known that they have about as much news value and are about as dramatic as the Ten Commandments.

The London Spectator offered a prize of five pounds for a four-line epigram on "The Modern World." The prize was awarded for the following quatrain:

Science finds out ingenious ways to kill
Strong men, and keep alive the weak and ill—
That these a sickly progeny may breed,
Too poor to tax, too numerous to feed.

Daddy Long Legs begins to have scientific value as applied to human beings, according to "release material" from certain universities to the press. Editors and news writers have gotten quite a "kick" out of the statements of "professors" that the length of the leg is proportionate to brain and mind capacity. Quite encouraging to men of the Lincolnesque type, but, as one editor says, what about the "Little Mac," the Harriman, and the Grant types. Then what about the long-shanked Africans? When it comes to the anthropological indexing of the female shank, Oh Boy! who would not like to be a "professor"?

"Big fleas have little fleas
Upon their backs to bite 'em;
Little fleas have lesser fleas,
And so ad infinitum."

This is about all of the news value that is left of the two-day front-page story about the fellow who "discovered" that even germs have parasites. That most all living things are both benefited and pestered by parasites and symbiotic associates has been known for generations. That this biologic phenomenon extended further than was demonstrated was no new doctrine. That a step, a useful step, forward in determining this phenomenon, as well as its significance when applied to some living things of microscopic size has been taken, is important. However, many, many hours of hard study and countless experi-

ments must yet be made before the road will be interesting or the work important to the average reader.

"Glandular Cure for Arthritis Claimed," reads the headline in one newspaper, and "Gland Tests Restore S. F. Derelicts," says another.

These and other headlines in other papers display a story that reads like—entirely too much like—a fairy tale:

"Gland transplantation, one of the foremost achievements of modern medical science," says one paper, "is to be credited with another series of almost miraculous cures as a result of experimental work carried on at the San Francisco Relief Home." . . . "Working under the direction of Dr. William C. Hassler, city health officer, for the last two years, Doctor Justin McCarthy has been so successful that he was able to state, in an interview today, that in more than 50 per cent of the arthritis cases treated the sufferers have found almost complete relief from pain." . . . "There have been any number of cases of inmates, bedridden and tortured for years by arthritis, who have been altogether relieved of pain," continues the interviewer. "Numerous Relief Home patients who have vainly tried every other remedy—milk injections, vaccines, and all the usual internal and external remedies—have been completely relieved."

If this story is even approximately true, most physicians will regret that the facts were not first released to scientific bodies of physicians. If the story is not true, the usual harm will follow. By the way, which particular kind of the several known types of arthritis of different causes and the others about which we do not know much will this new gland rejuvenation method cure?

Science or Sex Muckraking?—Some time ago we noticed a sex muckraking story about 1000 unmarried college women. The report claimed to show, as a result of a "confidential questionnaire," that many of them had, to paraphrase Kipling, "learned about men from him." A large number of these women admitted also, according to the report, to have played up and down the scale of abnormal sexual practices. The report contained nothing of special interest, nor that could be interpreted as surprising information to physicians, but psychologists and the general public seemed to get quite a "kick" out of the ramble through the fields of its salaciousness.

Now (Mental Hygiene), we have the second part of the story, dealing this time with 1000 married women of college and near college education grade. There are more of the same sort of figures and tables that tell of the sexual vagaries of the victims. Much of the effort of the "surveyors" appears to have been devoted to establishing what, if any, relation exists between the feelings engendered by masturbation and other self-inflicted sexual practices and those due to normal sexual intercourse. The average wholesome, clean-minded, non-medically educated person, after reading these reports, will want to take a bath.

The published conclusions from the extensive and expensive *survey* are about as sterile as any we have read for a long time.

Walter Camp died suddenly just after completing an article for a magazine, telling how simple it was to secure and maintain a status of the "pink of condition."

The death, thus dramatically, of the world's most aggressive "positive health," "live as long as you please" faddists, has been followed by a perfect orgie of controversy among physical culture faddists as to how it could possibly have happened.

Many newspapers are devoting considerable space to discussion of this subject by intelligent writers. The following abstracts from a series of such articles appearing in the Brooklyn Daily Eagle deserve notice. The author, Thomas S. Rice, says that "for many years physicians and other experienced observers have been calling attention to the dangers in much of the advertising propaganda for the immediate undertaking of daily, and more or less violent, exercise by those who have been inactive since boyhood or early manhood. *It is a serious menace to longevity, unless the individual who responded to the advertising limited himself strictly to what is recommended by a competent physician after thorough exami-*

nation, and with his recommendations carried out under the eye of a scientifically trained director.

"So vast has become the volume of reckless advice emanating from retired boxers, wrestlers, strong men and the like; and so many persons are enthusiastically going in for 'physical culture' without first consulting a physician, that it would seem a word of warning might well be issued by the daily periodical press.

"Has the cult of physical culture, carried to extreme as it now is being carried, done more harm than good in the way of shortening instead of prolonging human life? Observation extending over a number of years long ago convinced me that the professional exponents of physical culture are shortening the lives of thousands of valuable men and women. Issue will be joined by those who insist upon everybody keeping himself or herself fit by taking physical exercise every morning or evening, according to a schedule. They will urge that regular exercise is absolutely essential to those who wish to escape an early demise.

"We will agree that a certain amount of incidental exercise is essential, but we also believe that the physical culture exercise, especially for those who have not had previous training for many years, is a menace to longevity. Walter Camp's own death before he reached the sixty-seventh milestone will need a lot of explaining. . . . Physical culture adopted by middle-aged persons whose work has been more or less sedentary since boyhood, or early manhood, is an exceedingly dangerous undertaking for those who would wish to reach three score and ten. The extra strain upon the heart and arteries brought about through systematic physical exertion by those whose hearts and arteries may be said to have become 'set in their ways,' must inevitably have its effect, but very, very few physical culture enthusiasts, except in the best gymnasiums, make their warning clear to those whom they are so eager to proselyte.

"Anybody may set himself up as a physical culturist. Not only that, he may advise his clients, or whatever he may choose to call them, to pursue a course that must inevitably shorten their lives, and no check at all may be placed upon him.

"Any boxer, wrestler, football player, runner, shot-putter, etc., who has passed out of competition is privileged to open a gymnasium and tell the world that he is capable of giving fit instruction to all comers, regardless of their present apparent health or their past history. . . . Innumerable 'professors' are giving what they fondly call 'physical culture lessons' without requiring the applicant with fee in hand to consult a physician, and every such 'professor' should be suppressed.

"Many of the 'professors,' mostly those in the larger towns or cities, propose, but seldom compel, examination by a physician—and in a large percentage of cases it may be safely asserted that the examination has absolutely no effect upon the 'professor' or the client, in regard to the amount of exercise the client takes. The 'professor' may suggest that the client go easy for a while, or knock off for the day, but if the client asserts that he is feeling extra fine and wants to put in another hour of handball or handling the weights or the pulleys, does the 'professor' stop him for fear that the client may overstrain his heart? Not to any large and appreciable extent. . . .

"As a rule, the 'professor' not only refrains from checking overly ambitious or enthusiastic clients, but actually encourages them to speed up and prolong their exercise. No malice is intended. The 'professor' really believes he is helping the client by encouraging him to work briskly and frequently, and the more conscientious the 'professor,' the more harm he may do when his gymnasium is open to all comers of all ages.

"How frequently is a complete health history of the client obtained, reactions tested, urinalysis and blood examination made, and a careful series of tests and observations upon the client after violent exercise recorded as guides to future work in the gymnasium? Very rarely except in the big universities, and there the material is composed of boys or young men, with few or no middle-aged or elderly men in the problem."

The Brooklyn Eagle and Mr. Rice are rendering a fine and far-reaching service by such intelligent consideration of an important health subject. The practice of medi-

cine under the elastic title of Physical Education is just now the most widely promulgated cult. Like others, it is destined to be shortlived, and the shorter, the more lives spared. There is a legitimate field for physical education, but it is a comparatively narrow one and properly includes neither the practice of medicine on the one hand, nor the promotion of glorified sports and play on the other.

"Health Specialists" as "Go-Betweens"—There are interesting connections between some of the alleged health, beauty, dietetic, home economics, and similar columns and the freak advertising pages of some of the same publications. If you are interested in knowing about these connections, write and ask some of these alleged experts where and how to secure the things and the services they recommend. You are already more blasé and more completely disillusioned than most people ever get to be if you don't get some "kicks" out of some of your answers. Try the "radium products" promoting group; any of the "special" food or other group promoters and see what you get.

Rockefeller's Five Rules of Health—He follows as nearly as possible these health rules prescribed by his physician:

1. Don't worry.
2. Don't acquire overweight.
3. Drink three quarts of water every day.
4. Exercise.
5. Sleep in fresh air.

What Will We Do If We Should Get it?—William H. Welch, in an interview on his 75th birthday, is widely quoted as saying that "Heredity is a prime factor in determining the age to which a man should naturally live. There is reason to suppose that the span of life is inherited by definite laws."

Even the certain number of years that science can add to the human life, provided the individual works hard enough and constantly enough, brings added problems for society to solve, and, as Doctor Welch says, "longer life implies a certain measure of prosperity and of thrift. It also implies a higher popular intelligence."

About Birth Control—George Bernard Shaw says, according to the New York Times: "If people regard reproduction as an obscene subject, or a funny subject (and they are usually the same people), there is nothing more to be said: nothing remains but to live them down, and to be particularly careful meanwhile not to waste time, life and money in appeals to the law, which is always fifty years out of date. . . ."

"The shock I received at about 6 years of age, when, without any warning, I went into our drawing-room and saw a woman without a crinoline, probably produced a complex which psychoanalysts may be able to trace in my works to this day."

Havelock Ellis philosophizes thus: "'Birth Control,' indeed, and its substitutes—especially the latter—have been in active operation ever since birth began to take place on the earth, and even earlier, from the commencement of animal life. That is why it is possible to look at this question as one having an evolutionary meaning. . . ."

"A single oyster, if all its progeny survived, would speedily accumulate, it is estimated, a heap of shells eight times the size of the world. Even a pair of elephants, the slowest of all animals to breed, would in much less than a thousand years produce 90,000,000 elephants. . . ."

"The methods by which population is consciously or automatically controlled, and increase limited, are numerous. They fall into two groups, the first acting before conception, by decreasing fertility, and the second after conception, and indeed throughout life by increasing elimination."

Dr. Corrado Gini—"By means of special care and treatment, the weak and degenerate are, among modern civilized nations, saved from the selective action of nature and placed in a position to live and multiply."

Edward M. East—"Widespread rationalization of parentage will aid greatly in cutting down maternal and infant mortality, will effect a reduction of congenital defectives, and will lower the frequency of many diseases."

STIMULANTS, DEPRESSANTS, HUMOR

WHAT THE EDITOR HEARS ABOUT THE HISTORICAL NUMBER (MAY) OF CALIFORNIA AND WESTERN MEDICINE

Extracts from Letters and Other Messages

"It had to be good to stand out among a long series of excellent issues."—E. N. Ewer, President C. M. A.

"Better than I expected, and that is saying much."—John H. Graves.

"A splendid idea well carried out."—John Galloway.

"A finished example of highly pleasing and effective team work between editors and contributors."—James W. Ward.

"Not only our editor but our contributors are getting better all the time."—C. D. McGettigan.

"It does not contain enough about medicine."—M. D.

"It, as usual, promotes your friends."—M. D.

"I must take a minute of your time to congratulate you upon the excellent historical number of California and Western Medicine, May, 1925. In a great many ways our State Journal right now is unexcelled, thanks to your vigorous and wonderful management."—Frank Hinman.

Annals of Medical History

New York City, May 14.

"May we not congratulate you on the Historical Number of California and Western Medicine, which has greatly interested us and which we are sending to the editor for possible abstracting in the Annals of Medical History?"

We wish that you would send us two extra copies of this number that we may send to reviewers.

We note that you have other articles which were received too late for publication in this number. If they are to be published later, will you kindly send us marked copies of the numbers containing them?

We want to say that the Annals of Medical History will be glad to co-operate with you at all times in any medical history work. If we can help you, in the way of loaning cuts, etc., we shall be only too glad to do so."—Annals of Medical History, Paul B. Hoeber, Inc., publishers.

"You are to be greatly commended and congratulated for the manner in which you conduct our Association Journal, the type of papers presented, and greatest of all, the personal prefatory note given to many papers and the editorials. The latter always have my first attention with each new issue."

The Historical Number is excellent. It should be repeated. I hope you will continue for many years as our editor."—J. H. Woolsey.

"May I add to the numerous comments you must have already received, my very great appreciation of the Historical Number of California and Western Medicine? It is certainly a delightfully written, and an interesting and instructive compilation of fascinating articles, worthy of real litterateurs; and is particularly pleasing to me, for I am of a pioneer family and was born in San Francisco in 1861. I am familiar with many of the names and knew not a few of the splendid medical pioneers mentioned by Dr. Lyman."

One might easily get dangerously near exorbitant praise of Dr. Lyman's exceptionally fine handling of his subject, and the work of the other distinguished gentlemen who have lent so much to the success of the May issue, which should be perused by every Californian who truly loves his profession and his state."—Donald MacC. Gedge.

"Most hearty congratulations for the May number of California and Western Medicine. A most interesting and valuable addition to the library of any California physician."—Joseph Catton.

"I found the article on the early medical history of California intensely interesting and instructive. I never before realized what important roles physicians from the southern states played in the early California development. I am sure it will prove of equal interest to some of my southern doctor friends to whom I wish to send a copy of the Historical Number."

Please mail me a copy, for which I enclose 50 cents (stamps). Congratulations on the success of this interesting number."—Lindsay Peters.

"Permit me to congratulate you upon a most splendid production."

The illuminating and scholarly special article of Dr. George D. Lyman would grace the columns of any medical journal in the world. I suppose there were compelling reasons for omitting the bibliography of this paper, but I cannot refrain from expressing a regret that it did not also appear.

Concerning historical material in future issues of our Journal, my opinion is that a policy of collecting short authentic biographies of California medical men should be persistently followed by our state Journal, and from time to time the material so gathered should be edited and published.

I believe that our State Association, so far as the pages of its Journal are concerned, should allow the name of no practitioner of this state to go into complete oblivion. As the years roll by, the indices of our state Journal should reveal at least some little biographical record of every medical man who ever, for any considerable length of time, practiced his profession in California."—C. F. Griffin.

Medical Economics and Public Health

Veterans' Bureau Introduces an Innovation—In order to carry out the work of regional and hospital standardization of clinical and administrative service in the field, General Hines, director of the Veterans' Bureau, has just assigned four medical supervisors to a tour of field duty, with stations at New York, New Orleans, Chicago, and San Francisco.

To facilitate the handling of medical problems, it is the plan of the director to alternate field and central office service for staff physicians, so that they may become thoroughly familiar with all phases of medical administration both in the field and in central office, and also in order that the medical service may be completely standardized and uniform throughout. This plan was strongly endorsed at the last meeting of the Medical Council of the Bureau in February.

Dr. George O. Skinner, until recently acting manager of the District of Columbia regional office of the Bureau, will be stationed in San Francisco, his territory comprising the states of Montana, Wyoming, Colorado, New Mexico, Utah, Arizona, Nevada, California, Oregon, Idaho, and Washington.

It is a mystery why lay organizations which promote public health persist in ignoring the practicing physicians of their communities. A great criticism of public health nursing is, that the nurses diagnose and treat cases of sickness. While it is true that the cases which most nurses diagnose and treat are mild and are those which a physician does not usually care to visit, yet who shall draw the line?—Editorial, New York State Journal of Medicine.

The "Middle Man" in Medicine in Action—"There may be a few Indiana doctors," says the Journal Indiana Medical Association editorially, "who are connected with health institutes and who make health examinations of persons who have applied to the institute for such service and the reports of which are passed on to the institute for analysis before results of the examination are reported to the patient who pays handsomely for the advice. Just why any physician should consent to be a go-between is hard to explain, but the worst feature of the business is that the patient is being imposed upon, and the doctor who makes the examination is contributing to the success of a commercial enterprise that does not deserve recognition at the hands of ethical medical men. Periodical health examinations are becoming justly popular, but if they are going to fulfill their purpose they must be controlled by the medical profession, and any suggestions or advice given the patient should come from the physician making the examination and not in a round-about way through a commercial agency."

Note the Italics—An Eastern state now has a law which, according to official publications, "authorizes *boards of education* and school trustees to provide transportation; home teaching; special classes or special schools; scholarships in non-residence schools; tuition and maintenance in elementary, secondary, higher, special and technical schools and, on recommendation of the State Department of Health, *surgical, medical or therapeutic treatment, hospital care, braces, and other appliances* for physically handicapped children."

And yet some people still claim that public school systems are not even interested in the practice of medicine.

How Can a Christian Science Healer Consistently Sign a Certificate of Illness—In answer to this question, the chairman of the Christian Science Committee on Publication answers in part (Colorado Medicine):

"Christian Science naturally and consistently deduces that whatever does not speak of the goodness and harmony of God is but an expression of erring human sense. Sickness is very real to the human sense, but no one can

reasonably claim that sickness is eternal and a part of the absolute reality of being in God's sight, for if it were we could never be rid of sickness. From this it will be seen that the therapy of Christian Science does not consist of, nor depend upon a negative premise, but rather does it operate from the affirmative spiritual facts about God and His creation. Thus Christian Scientists obey Jesus' counsel to 'render unto Caesar the things that are Caesar's by signing certificates of illness and also 'render unto God the things that are God's' by endeavoring in their prayer or treatment to 'know the truth,' which Christ Jesus said would make men free."

To which the editor of Colorado Medicine adds:

"*Reply*—Despite the foregoing explanation, we remain a little hazy concerning the mechanism of Christian Science.

"A man cuts his knee and his trousers. He admits the cut on his clothing, but not in his flesh. A woman has a wart on her nose. She denies the existence of the wart, but acknowledges the reality of the nose.

"Here is a form of differential nihilism in which the credulous mind denies or affirms the existence of things according to caprice.

"We prefer the more critical analysis of the bard:

"There was a faith healer of Deal
Who said, 'Although pain isn't real,
If I sit on a pin,
And it punctures my skin,
I dislike what I fancy I feel.'"

Many Doctors Might Save Money by Reading This—No medical man thoroughly appreciates the hazards of his profession until he has been sued. Your counsel has observed the psychology of countless doctors who have been forced for days at a time to drop their practice and to hear themselves presented in court as the villain of the piece, watching with chagrin, amazement and concern the unfolding of their alleged shortcomings. The possession of insurance, under such circumstances, in addition to the knowledge that their rights will be safeguarded in court, is a source of assurance, confidence and consolation which only those who have been sued fully understand and appreciate. . . .

The question fairly arises for all doctors, both those with years of experience and those who are just embarking upon their professional career: Is it safe to practice medicine without being insured?—Attorney Whiteside, New York State Journal of Medicine.

Protecting the Health of San Franciscans—The new budget of the official San Francisco Health Department shows that one out of every 500 citizens of the county is an officer or employee of the department charged with protecting us against dangers to health. The cost of this service is some \$3.50 a year per person. Assuming that the work is well done, and we are not intimating otherwise, the cost is a reasonable one. Few citizens take the trouble to understand the fact that this is only one of the several official government agencies with other hundreds of employees also largely engaged in keeping us from getting sick. Nor do most of us connect the activities and expenses of OFFICIAL health-protecting agencies with the vastly more numerous persons engaged in and the vastly greater sums of money being spent in the same service by VOLUNTARY health organizations and individuals who are engaged privately in health work for a livelihood. The group of voluntary health betterment organizations which some of the leaders claim to constitute the "*unofficial government*" in places expend more money and employ more helpers than does the "*official government*" board.

The group of individuals and organizations who are engaged in keeping San Franciscans well and getting us well for a livelihood includes physicians (1 to 450 of population), nurses (1 to 1000 of population), technical and clerical help (1 to 500 of population), and several other classes not here enumerated. It may be that the time of more than 10 per cent of our population is necessary to protect the health of the 100 per cent, but one of these days it is going to become *very* difficult to explain why so many people employed by so many different groups, official and unofficial, are being paid to do pre-

cisely the same things. What has been designated as "*charity in business*" and "*business in charity*" movements are so rapidly assuming the same sort of "refrigerated" lines of development that it is becoming difficult to distinguish between them. However, our official health authorities should have their money.

The A. M. A. List of Approved Hospitals—The American Medical Association, through its Council on Medical Education and Hospitals, which handles the hospital work for the association, has issued its 1925 revised list of hospitals approved for internships. The list is published in the *Journal of the American Medical Association* for March 28. It will also appear in the ninth edition of the *American Medical Directory*, besides being in separate pamphlet form. The list names 524 hospitals that are in position to furnish general internships, such as satisfy the medical colleges and state boards, as well as meet the almost universal demand of medical graduates for at least a year's general hospital experience, practice or specialization.

There were reported 5059 interns, of whom 3825 are in the 524 approved hospitals, and 1234 interns in 2696 non-approved hospitals. This total of 5059 interns compares favorably with the 3669 interns reported in the census of one year ago, the increase being 1390 or 37.9 per cent. In fact, there are 156 more interns now in approved hospitals than there were in all hospitals two years ago.

When the hospitals began to feel the shortage of interns about a decade ago, they quite naturally resorted to pecuniary appeals and offered salaries, usually ranging from \$25 to \$100 per month and maintenance. Now the appeal must be made on the basis of educational opportunities offered rather than financial remuneration. There are still a number of hospitals that pay their interns, and there can be no objection to giving interns some financial help, but hospitals which secure the best interns and most easily are those whose staffs are known to furnish the best educational opportunities, salary or no salary. The Council on Medical Education and Hospitals also publishes a list of the hospitals that provide approved residencies in specialties for those who have already had a general internship or experience.

By furnishing these lists the council serves not only those who are seeking an internship or residency; it also contributes much to the good of the profession and the public by encouraging a broad general foundation, both for general practice and for specialization.

Did You Receive One?—Some self-respecting physicians are receiving letters from another New York doctor who wants to add California to his list of supporters, inviting them to "practice my method" of treating errors of refraction without glasses. The letters are signed —, M. D.

Commending State Medicine—"The hospital policy of the state (Colorado) is to be especially commended," says George E. Vincent (*Colorado Medicine*). "Colorado aligns herself with other states, notably Michigan and Iowa, which assemble in a specialized university-controlled hospital needy sick from the entire commonwealth. A budget made up of legislative appropriations, county funds and patients' fees supports the institutions which at the same time provide excellent medical and surgical care and favorable facilities for education. . . . There is much cynicism abroad about the popular understanding and appreciation of science. The willingness of a few legislatures to vote on evolution, the gullibility of whole populations with respect to quack remedies and fraudulent stocks, the too ready acceptance of campaign sophistries are cited as evidences that the people are uncritical and powerless to protect themselves against propaganda.

. . . "If the university graduates—lawyers, teachers, successful business men, clergymen—if women of prominence in social and professional life, in clubs and philanthropy, accept uncritically 'Sunday-supplement science,' unverified testimony about 'cures,' blatantly advertised remedies, most of which at best are useless, and put them-

selves in the hands of doctors of dubious standing or of miscellaneous healers, what hope is there of creating a congenial environment for true science and its devotees?

. . . "There are experts and 'experts.' The popular distrust of experts is significant of several things. In a democratic society, one who professes to know more than the average man is naturally resented and disliked.

. . . "Human personality is complex; motives are mixed. All good qualities and all bad do not come in neatly separated bundles. They are variously assorted. Judgment must try to determine the predominant and guiding purpose of a given personality."

Chief Surgeon Morrison of the Atchison, Topeka & Santa Fe Railway Company, announces the following appointments, effective April 1: A. Schloss, district surgeon; Alson R. Kilgore, local surgeon; E. S. Kilgore, Wallace I. Terry, Gilbert M. Barrett, consultants. The physicians and surgeons named above all have headquarters at San Francisco. Dr. Schloss, newly appointed district surgeon, has been attached to the staff of the Medical Department of the Santa Fe for the past twenty years. The other appointees are well-known physicians, surgeons, and specialists.

The Nestle's Food Company, who are appreciated advertisers in *CALIFORNIA AND WESTERN MEDICINE*, submit as their contribution to the advancement of scientific infant-feeding, Nestle's Lactogen—the natural food for infants.

"Lactogen," writes Doctor W. E. J. Kirk, medical director Nestle's Food Company, "is a homogenized, scientifically desiccated, full-cream cow's milk, manufactured primarily for the feeding of infants from birth to six months of age, who, for any reason, are denied the privilege of breast-feeding. It is peculiarly adapted for infant-feeding, owing to its close approximation to breast milk in composition, digestion and assimilation, thereby supplying a rapidly increasing demand from the medical profession for a desiccated milk of superior quality and unquestionable safeness, wholesomeness, and nutritional value.

Physicians will be interested to know that Lactogen is marketed only on an ethical basis. No feeding instructions appear on the trade package, and no literature is mailed to the laity.

Analysis, complete suggestions for the dilution and feeding of Lactogen, together with comparative analyses and caloric values, are mailed physicians upon request.

The Physiological Treatment of Hay-Fever—It is now widely known that hay-fever is due to the hypersensibility of the patient toward one or more foreign proteins, generally those of the pollens of neglected and useless weeds. Therefore, this fact must be kept in mind in the treatment of this disease. The pestiferous pollens are usually present in all parts of the United States between June 1 and September 1. They are present in the atmosphere, being wind-blown, the patient inhaling them into the nose. The pollens adhere to the sensitive and moist mucous membranes, and if they are allowed to remain and penetrate the surface, soon set up an irritation and inflammatory condition of the terminal nerve filaments which quickly spreads widely through the air passages.

In order to prevent the development and liberation of the poisonous proteins of the pollens, many physicians prescribe irrigation of the nasal channel from one to several times a day, thus washing them out as fast as they accumulate.

This cleansing process is easily and comfortably accomplished by the Nichol's nasal syphon, about which further information will be found monthly in our advertising pages, which suggests itself as a safe and sure device, owing to its unique suction action. In fact, whatever treatment is prescribed, the device will prove an additional aid, inasmuch as it dissolves and draws out the pollen carrying secretions by irrigation.

After each irrigation, it is recommended that a bland oil should be used with an atomizer. This acts as a prophylactic, as it covers the membranes with an oil coating

which prevents the pollens from adhering to them and starting the irritation.

Medical Profession Found Constant in Recognizing Merit—"Some of the older pharmaceutical houses tell us," say the Deschell Laboratories, whose advertising is found in CALIFORNIA AND WESTERN MEDICINE each month, "that the medical profession are fickle; that they will prescribe an article for a while and then leave it to take up something else.

We have investigated this very carefully and have come to the conclusion that the medical profession are very constant, recognizing merit wherever it may be; use a good article over long periods of time, and stop using it only when something better is available.

The houses that are abandoning the medical profession and advertising their products to the public (some of them under the guise of household remedies, all of them, however, tending to encourage self-medication), are the ones that state the medical profession are fickle.

We find that where quality is maintained; where strict ethical merchandising methods are followed, the profession is loyal. But where unscrupulous houses put out a good article at first, then decrease the quality and start advertising to the public, they cannot expect to carry water on both shoulders and keep the loyalty and support of the medical profession.

We take this instance to pledge our loyalty to the medical profession in the manner of our merchandising and in the constant effort to preserve the high quality of our product.

Ampoule Solutions Daily Growing in Popularity—

The ampoules that are particularly to be recommended are made of imported glass, glass containing no soluble alkali that might have an effect upon the medicament. The ampoules, after being filled, are closed hermetically under a gas flame; in other words, the glass at the neck is melted and fused, and the container is thus made air-tight and water-tight. In addition to this protection, it is necessary in some cases to protect the solution from the effect of light, and the ampoules are, therefore, put up in cardboard cartons which exclude the light.

All of which goes to show that conveniences are not gratuitous, but must be paid for by either the manufacturer or the user. In this case the manufacturer pays the major part of the price in the care required for assaying, sterilizing and encasing the medicinal solutions; but the user is supposed to keep the ampoules in their respective packages, and not let them lie around loose, until they are needed. In some cases, too, it is quite important that the date stamped on the package be consulted, for the ampouled solutions are not all indefinitely stable. This reasonable care cannot be considered a high price to pay for the convenience of having at hand a sterilized solution in individual doses for subcutaneous, intramuscular, or intravenous administration.

Some of the merits of this class of products are tersely set forth in the advertisement on "Ampoules," by Parke, Davis & Co., which appeared in the April issue of CALIFORNIA AND WESTERN MEDICINE.

What Would Similar Tests Show for San Francisco and Los Angeles?—"The air breathed in downtown Chicago contains eight times as much dust and twenty times as many bacteria as air in the suburbs. These facts are the result of elaborate health department tests."

"The Investment Banker," writes Mr. R. B. F. Randolph, vice-president Anglo London Paris Company of San Francisco, "finds, in his endeavor to serve the community, that the physician and surgeon is probably the hardest person to get at for the purpose of talking investments, and yet practically the greatest part of his daily work hinges on appointments. It is, of course, one of these peculiar situations, and one which we all appreciate, that the professional man constantly has his mind on professional matters, and rarely has time for his own personal business affairs; accordingly, these must necessarily be neglected to an extent.

This situation is an unfortunate one, yet, nevertheless,

seems to be true in many instances, and the accumulation of surplus funds should, therefore, be invested under the advice of investment specialists, as it is quite possible that the investor neither has the time to acquaint himself with prevailing market conditions, nor perhaps has made sufficient study of the security market to enable him to make safe and profitable investments, and it is just possible that those securities already held should be reviewed and analyzed and suggestions made, where necessary, as to reinvestment.

No doubt some may feel that the representatives of various investment companies have perhaps been over-persistent in their endeavors to make appointments to discuss investments, but a short time used in this manner may be the means of a considerable saving, insofar as present holdings are concerned, or a suggestion given for the employment of idle or surplus funds. The officers and representatives of the Anglo London Paris Company are at all times available for consultation in this respect, either at their office or at yours, and will be glad to make suggestions as to sound investments and also through the recent establishment of an analysis division, properly analyze present holdings and advise impartially as to reinvestment when necessary. Their announcement is found in the advertising pages of CALIFORNIA AND WESTERN MEDICINE every month.

Intestinal Parasites Among Filipino Food Handlers

—Many of the Filipinos that come to the United States find employment in the handling of food supplies. In the public institution surveyed by Harry A. Wyckoff and William O. French, San Francisco (Journal A. M. A.), some of them are employed as waiters, as bus boys, and in the kitchen. Out of thirty-four cases examined, twenty-eight were found positive for parasites. Twenty-two of these positive patients harbored either a double or triple infestation. The parasites found were hookworm, in twenty-one cases; trichuris, sixteen cases; ascariis, two cases; fasciolopsis and hymenolepis in one case each, and protozoa in twelve cases. Compared with the incidence of intestinal protozoa in medical patients in the Stanford Hospital the percentage of infested Filipinos is greatly in excess. The number of positive findings among hospital and clinical patients was found to be 22 per cent in 7000 patients examined. Only 4 per cent harbored helminths. Among the Filipinos, 72.4 per cent were infested with hookworm and 42.9 per cent with protozoa. All the hookworm patients were given routine treatment with carbon tetrachlorid. Nineteen patients were treated for hookworm. Adult worms were removed in fourteen cases. Adult ascariids were found in two cases, and the ova in three cases. Trichuris ova were recovered in six cases. hymenolepis and fasciolopsis ova in one case each. Protozoa alone were found in four cases. The number of hookworms recovered were small, although one case yielded sixty-seven worms. Ascariids were recovered by this treatment in two out of three patients infested. Fourteen patients treated with carbon tetrachlorid were re-examined two months later. No ova of either hookworm or ascariis was found. The carbon tetrachlorid did not affect any of the other worms or protozoa. The only toxic symptoms noted as a result of this treatment were nausea and vomiting in six patients, and dizziness with headache in two patients. All, however, except two, could be discharged the next morning, although some were unable to carry on their duties the following day. Carbon tetrachlorid did not always act as a cathartic. In many cases there were no evacuations or only one evacuation in the eighteen hours following administration. In the majority of cases in which there was only one stool, or in which an enema was needed, the patients were nauseated or vomited.

"The tendency to centralize government at Washington," Senator Borah recently declared, "is undermining the confidence and destroying the capacity of the citizen to assume and meet the duties and obligations of citizenship. There is not a practice, custom or habit but must soon be censored from Washington. There is not in all the relationship of parent and child, of family and home, anything sufficiently private and sacred to exempt it from the furtive eye of the special agent."

California Medical Association

EDWARD N. EWER, M. D., Oakland.....President
 W. T. McARTHUR, M. D.....President-Elect
 EMMA W. POPE, M. D., San Francisco.....
Secretary and Associate Editor for California

ALAMEDA COUNTY

Alameda County News (reported by P. S. Nusbaumer, secretary Alameda County Medical Association)—At the regular monthly meeting of the Association, held April 20, 1925, F. J. Carlson reported a case, dislocation of the shoulder, with exhibition of the patient, and Lindsay Peters reported results of insulin treatment in a case of diabetes mellitus complicated by pregnancy and funnel pelvis. The regular program was a symposium on cancer by members of the Fabiola Hospital staff, H. D. Bell, chairman. The first paper was by Daniel Crosby, entitled "Solid Cancer of the Ovary." Crosby discussed the pathology and various classifications of ovarian cancers, following which he reported a case in which a large solid carcinoma of the ovary was discovered during an abdominal section for other causes. This case was complicated by a diffuse adeno-carcinoma of the body of the uterus. The affected ovary, tube and uterus were removed. The patient was treated with radium, and has no evidence of recurrence three years and six months after operation. Gertrude Moore discussed this paper from the pathological standpoint. In his discussion of the paper, E. H. Barbera also reported a case of solid carcinoma of the ovary. Dr. Ewer's subject was "Cancer of the Uterus." Ewer pointed out the lines of extension of the different varieties of cancer of the uterus and their bearing upon diagnosis of operability. In connection with operability, the value of the Ruge-Phillip test to determine virulence of streptococci in the degenerating mass was pointed out. Streptococcic peritonitis, the cause of most operative deaths, follows when virulent strains of the organisms are present, in a very large percentage of cases. The technique of radium treatment in several Eastern clinics was described. The discussion of the paper was opened by L. P. Adams. In his paper on "Cancer of the Stomach," R. T. Sutherland emphasized the need for earlier diagnosis and treatment of gastric cancer. Because of the very insidious onset in most cases, greater attention should be paid to a careful history of so-called dyspepsia in patients over 30 years of age, together with scrutinizing examinations of all such patients. He stated that in many of these patients the earliest symptoms may be either loss of weight, anorexia, weakness, or pallor. He advises that frequent gastric examinations, together with fluoroscopic and roentgen-ray examinations, should be employed in all suspicious cases, and if doubt of cancer exists, early exploratory operations are justifiable. This paper was discussed by Guy H. Liliencrantz and C. E. Peters. At the conclusion of the scientific program the business matters were taken up; new members introduced by the president, announcements made; after adjournment, refreshments and a social hour.

Providence Hospital Staff—The annual banquet of the Providence Hospital staff was held at the Hotel Oakland, May 7, with some sixty-five members attending. O. D. Hamlin presided. H. B. Mehrmann extended greetings. J. Wilson Shiels was the speaker of the evening. Among other things, he emphasized the importance of the medical man joining the United States Medical Reserve Corps. There was good music, both vocal and instrumental. All agreed that it was an evening long to be remembered.

Fabiola Hospital—At the first annual reunion of the graduate nurses of Fabiola Hospital, held recently at the nurses' home of the Fabiola Hospital, 200 nurses were present and were welcomed by Mrs. J. P. H. Dunn, president of the Fabiola Hospital Association. The celebration opened with a supper and entertainment given in the auditorium of the home. The nurses came from all parts of the state for the occasion. Many of the first

graduates of the Fabiola Hospital Training School traced the progress of the institution since its foundation thirty-seven years ago, when their Alma Mater was the first established in Oakland. There are now 500 graduate nurses, many of whom are still in active service.

A notable feature of the banquet program was a parade of the different uniforms, which were worn by the nurses during their training in the earliest days of the school, in which every branch of nursing is taught.

On May 1 a luncheon was given in Mosswood Park by the alumnae for all the graduates, and in the evening the graduation exercises were held in the auditorium of the nurses' home, when fourteen young women received their diplomas.

~

CONTRA COSTA COUNTY

Contra Costa County Society (reported by L. St. John Hely, secretary)—The regular monthly meeting was held Saturday evening, April 25, at the Hotel Los Medanos at Pittsburg. The society were the hosts of Drs. Gregory and Blackshaw. A dainty lunch was served the members in the main dining-room of the hotel.

Dr. S. H. Buteau read a paper on "Acute Abdomen." The subject was discussed at length by nearly all the members. Never in the history of the society was a subject so important or interesting brought before the members. Dr. Buteau brought out every possible complication and emergency that may arise in meeting with such a case, and what he did not bring out the members did. In all, we consider that we spent a most profitable evening.

One new member was enrolled on the list, in the name of David C. Wise of Pittsburg. We think he is going to be a valuable addition to the roll.

The members, by unanimous vote, ordered the secretary to forward a vote of thanks and appreciation to the assistant district attorney, congratulating him on his successful prosecution of Cosper in the Dietrich case.

The following members and visitors were present: S. H. Marks, Pittsburg; L. A. Clary, San Francisco; G. M. Bumgarner, Richmond; E. C. Love, Danville; H. L. Carpenter, Richmond; J. Edward Clark, Walnut Creek; George McKenzie, Concord; W. C. Robins, Brentwood; Denninger-Keser, Richmond; L. St. John Hely, Richmond; H. W. Stirewalt, Walnut Creek; John Beard, Martinez; H. L. Gregory, Pittsburg; D. C. Wise, Pittsburg; C. L. Abbott, Richmond; S. H. Buteau, Oakland; Mrs. E. C. Love; Mrs. John Beard.

~

FRESNO COUNTY

Fresno County Medical Society (reported by T. Floyd Bell, secretary)—The monthly luncheon of the Fresno County Medical Society was held April 18 at the Hotel Fresno. There were twenty-three members present, as follows: Members—Drs. Aller, Anderson, Barr, Bell, Binkley, Butin, Cross, Dahlgren, Dau, James, Montgomery, Mitchell, Morgan, Madden, Nider, Newbecker, Pettis, Pomey, Pisor, Schottstaedt, Sciaroni, and Sheldon. Miss Taylor, R. N., of Madera was a guest of the society.

In the matter of examining those pre-school children who could not come to any doctor's office, Madden moved, Mitchell seconded, that a volunteer committee of doctors be appointed to examine such children at convenient places to be designated later. Carried. P. S. Barrett was named chairman.

Pettis moved, James seconded, that a committee of two be appointed to make a suitable placard for offices announcing the Saturday afternoon closing, and also have same published in the local press. Pettis and Mitchell were appointed.

R. W. Binkley, a member of this society, was the speaker, his subject being "The Variation of Medical Fees According to the Ability of the Patient to Pay." He first talked about the financial status of doctors, and said that, as a class, they were failures as business men. The doctor is not trained in the business part of his profession. The "old doctor" did not send out monthly statements and try to collect money justly due him. Consequently, he collected barely enough to live on, and his children many times actually had to work to help support the family. The doctor should collect money for his services

just as any other business man does when he sells his commodity, for the doctor's services are his commodity. Insurance statistics show that more doctors die leaving nothing but life insurance than any other profession, not excepting teachers and preachers.

Up to a few years ago medical economics had no place in medical meetings. Doctors were interested in presenting new problems or the solution of such problems, and the advance made in the science of medicine. But finally someone had the courage to bring up the "Business Methods of Doctors." They called in efficiency experts, not doctors, to consider this matter and make a report. These experts found that over 50 per cent of the widows of doctors are working for the necessities of life, and that the age of doctors is 45. They reported also that doctors give seven times as much to charity as any other man of similar income, and that they donated not only money, but service. What other business man would do this? These lax business methods would bankrupt any other business in less than a year. They drew up a fee schedule, which is much higher than that used today, based on the ability of the patient to pay. They showed that the responsibility and risk of caring for the rich was much greater than for the poor. Therefore, they advised that a man with moderate income should pay a moderate fee, a poor man none or a small fee, and a rich man a large fee.

Dr. Binkley showed a curve of the doctor's income at various ages. This showed the peak of the greatest income at the age of 45. After this age it dropped rapidly to 55. The necessity of spending about ten years at the beginning on medical training and the inability to keep up to the standard one's earning capacity at the end of life makes the earning time of the doctor very short. He must make his money during this short period or suffer financially. His business is unlike the ordinary business. When he builds it up he must be there to run it or else it is worthless.

The regular meeting of the Board of Governors of the Fresno County Medical Society was held May 4, in Dr. Anderson's office.

Couey, Cross, Miller, Trowbridge, Anderson, and Bell were present.

Bills were audited and ordered paid.

Miller moved, Trowbridge seconded, that the secretary deposit as much money as he thinks best in the savings department of the United Bank and Trust Company. Carried.

Cross moved, Trowbridge seconded, that the placards for Saturday afternoon closing be printed and distributed, 120 in number.

Anderson reported in regard to the recent visit here of a representative from the State Board of Medical Examiners, who came to investigate the alleged violation of the Medical Practice Act of the nurses of the Sun-Maid Welfare League. He believed the matter to be settled satisfactorily.

Cross moved, Trowbridge seconded, that the resolution of April 6, 1925, in re investigation of admission to the General Hospital, be amended to include the City Emergency Hospital, and that the number of the committee be increased to five. Carried.

The secretary was instructed to write the American Legion Auxiliary Unit No. 4 that we sanction the "Better Baby Show," but do not advise it.

Miller moved, Trowbridge seconded, that it be considered unethical for any member of this society to deliver lectures at stores or similar places on professional topics. Carried.

The secretary was instructed to write the Fireman's Benefit Fund that the board felt that the amount of fee is entirely inadequate to cover services required.

The regular meeting of the Fresno County Medical Society was held May 5, at the Hotel Fresno.

There were twenty-five members and thirty-one visitors present.

Members—Drs. Aller, Anderson, Bell, Couey, Cross, H. O. Collins, Dau, Barr, Hare, Konigsmacher, Lamkin, Larson, Manson, Mathewson, Montgomery, Mitchell, Morgan, Milholland, Madden, Nider, Newbecker, Pettis, Schottstaedt, Sciaroni, Thompson, and Willson.

Because of the large number of invited guests, the regular order of business was dispensed with.

The secretary was instructed to cast a ballot for Dr.

J. M. Frawley, his application having been passed on favorably by the board of censors and the state secretary.

Cross presented the following resolution, to be sent to the State Board of Medical Examiners. On motion of Madden, seconded by Milholland, it was carried:

"We, the members of the Fresno County Medical Society, desire to enter a protest to your Honorable Members, in the matter of the employment of narcotic addicts by the State Board of Pharmacy to act as stool-pigeons.

"Recently one C. Bentley, who committed suicide in the jail located in Modesto, California, was used by the said Board of Pharmacy to visit the offices of physicians in this city. His method was to appeal to said physicians as a suffering human requiring relief from pain.

"We deplore the use of these unfortunates for such purpose, as it would appear to encourage them in their habit, as it is known that persons suffering from such habits cannot be trusted with drugs to which they have become a slave.

"We feel it unjust that the license of a practicing physician should be jeopardized who, in the kindness of his heart, is induced to prescribe, under misrepresentation, for such people.

"With the furnishing of narcotics to addicts for gain or the careless dispensing we have no patience, but to the unfair method of using these people to trap a physician during his busy hours when he may be caught off his guard, we consider unfair.

"If it does not come within your province to deal with this situation, will you kindly forward this communication to those who have jurisdiction?"

Cross moved, Morgan seconded, that the new constitution and by-laws, as presented at the last regular meeting, be adopted. Carried.

The meeting was conducted in celebration of "Cancer Week." To give publicity to this subject each member was asked to bring one or two laymen as guests. The speaker was Dr. Alson R. Kilgore of San Francisco, the representative of the American Society for the Control of Cancer. The first part of his talk was devoted to "Some Blue-Sky methods in Medicine," in which he discussed various quack cancer cures, such as arsenic paste, sera, coagulum, and diet. He emphasized the fact that all these methods of treatment are dangerous because they put off the day of proper treatment till it is too late to cure. This part of the program was especially for the lay people present. Kilgore then took up some newer aspects of the cancer problem, dealing mainly with breast cancer and pre-cancerous lesions in the breast. He illustrated this part of his talk by lantern slides.

There were several musical numbers by local artists, after which a buffet luncheon was served.

✽

MARIN COUNTY

Marin County Medical Society (reported by J. H. Kuser, secretary)—On April 23, at the San Rafael Club, Samuel Hurwitz of San Francisco presented a paper before the Marin County Society. The following members were present: H. Hund, W. F. Jones, R. Furlong, L. Landrock, Charna Perry, U. W. Clark, J. H. Kuser.

Dr. Hurwitz's paper was followed by an interesting discussion. The business meeting was postponed until the next regular session.

Examination of pre-school children by the members of the Marin County Medical Society was undertaken and successfully carried out in the week from April 20 to 24.

✽

ORANGE COUNTY

Orange County Medical Association (reported by D. R. Ball, secretary)—The regular monthly meeting was held the evening of March 3 at the Orange County Hospital. D. A. Harwood of Santa Ana read an interesting paper on "Ruptured Uterus Following Caesarean Section." The factors at the time of surgical delivery that make for subsequent rupture were discussed. Following this, a plan of procedure for the conduct of later pregnancies and labors was outlined. The doctor advocated the test of labor under supervision rather than the unqualified acceptance of the dictum "Once a Caesarean section, always a Caesarean section." The second paper of the evening was read by G. I. Sellar of Fullerton on

"The Ear and the General Practitioner." The reader discussed the conditions of the external and middle ear commonly met with and the treatment of these conditions. The business included the election of three new members: G. I. Sellon and F. H. Gobar of Fullerton, the former a transfer from Custer County, Nebraska, and J. D. Ball of Santa Ana.

The April meeting was held at the Orange County Hospital on the evening of the 7th. The society had as its guests District 16 of the California Nurses' Association, together with the other nursing organizations of the county. The address of the evening was given by Dr. Lela J. Beebe of the State Bureau of Child Hygiene. The speaker first outlined the great strides that have been made in recent years in the prolongation of human life, and mentioned new problems that this added longevity has brought up. She then proceeded to outline the work that her department is carrying on in this state. The work is divided into four main groups, and includes: First, improving the quality of prenatal care; second, maintenance of breast-feeding and where this is impossible, proper artificial feeding under medical supervision; third, spreading among the laity the knowledge of fundamental health habits; and fourth, the necessity of periodic health examinations. Dr. Beebe's talk provided a stimulus for all of us to renew our work in these large fields. A general discussion of public health problems followed, and the meeting was closed with an enjoyable "feed."

The Santa Ana Clinical Society has recently listened to two very interesting speakers. C. E. Phillips of Los Angeles discussed the subject of "Gall-Bladder Disease" at the March meeting. The speaker first made the point that gall-bladder disease is now accepted as a surgical disease, and then went on to discuss certain difficulties that arise in diagnosis, and finally discussed the operative procedure. V. R. Mason, also of Los Angeles, spoke on "Observations on Gastro-Intestinal Disease" at the April meeting. Subjects touched on by the speaker in an original way included gastric tetany, peptic ulcer, intestinal flagellates, and anebic dysentery. Both of these talks were valuable, in that they were not set papers, but rather observations taken from the large experiences of these men in their respective fields.

PLACER COUNTY

Placer County Medical Society (reported by Robert A. Peers, secretary)—The society held its regular May meeting in the reception-room of the Placer County Hospital, Saturday evening, May 9, President H. N. Miner presiding. There were present the following members and visitors: E. H. Bryan, C. E. Lewis, H. N. Miner, H. M. Kaner, J. A. Russell, F. L. Fanning, R. H. Eveleth, L. B. Barnes, R. A. Peers. Visitors: F. F. Gundrum, C. E. Von Geldern.

Dr. Bryan presented to the society a five weeks' old infant suffering from spina bifida. Gundrum addressed the society on the subject of the "Medical Aspects of Arteriosclerosis," going into detail as to the pathology, etiology, symptoms, prognosis and treatment of the various types, after which Von Geldern discussed "The Relation of High Blood Pressure to Industrial Medicine." Both addresses were discussed by all members present.

RIVERSIDE COUNTY

Riverside County Medical Society—(reported by T. A. Card, secretary)—The regular meeting of the Riverside County Medical Society was held in the Riverside Community Hospital on May 11.

It was decided that the June meeting would be an open social meeting in the form of an outdoor gathering at the Rainbow Angling Club, where the members and their families could enjoy themselves fishing and later have a trout dinner. This form of outdoor meeting has been carried on for the past five years, and has become an annual affair with our society. We are looking forward to a general good time.

The program of the May meeting was as follows:

Case Report: "Esophageal Stricture in an Infant"—Paul F. Thuresson, M. D., Riverside.

"What Do We Know About High Blood Pressure?"—W. W. Roblee, M. D., Riverside.

"Pneumonia in Children"—Joseph Robinson, M. D., Anaheim.

The meeting was well attended, and a free discussion was participated in by the members present.

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement—(reported by Bert S. Thomas, secretary)—The April meeting was held at the Hotel Sacramento on the 20th. Forty-two members and fourteen visitors were in attendance. The latter included Dr. Peers from Colfax and Dr. Thoren from Weimar. A number of local clinical workers in tuberculosis augmented the number to hear the speaker of the evening, Dr. F. M. Pottenger of Monrovia. The minutes of the February meeting were read, and, after one correction in Dr. Schoff's remarks at that meeting, they were approved. There was no presentation of cases, and the meeting was immediately turned over to Doctor Pottenger, who spoke upon "The Classification of Symptoms of Important Internal Viscera." A brief synopsis of his subject follows:

"Pathologic anatomy has dominated medicine for the seventy-five years past; in fact, it has been considered the essence of medicine. The clinician, however, in his every-day practice, is not dealing so much with pathologic anatomy as pathologic physiology. Symptoms of diseases are manifested as disturbed function, and disturbed function does not ever occur until the normal physiologic equilibrium is upset.

"In order to understand symptoms, it is necessary to understand the normal physiologic control of the body. This control is a threefold mechanism, depending upon: (1) The cells, their physical state and ionic content; (2) the nervous system; and (3) the chemical substances which come in contact with the cells, hormones, oxygen, and all the products of secretion and excretion.

"Most symptoms of disease, aside from those of the voluntary nervous system, are expressed on the part of some of the important viscera, such as the nose, pharynx, larynx, heart, lungs, kidneys, bladder, and organs of the gastro-intestinal and genital tracts. While these organs may not be the seat of the disease, symptoms on the part of these viscera nevertheless appear.

"Therefore, it is necessary for us to understand the physiologic relationships which govern the action of these organs, and bind them to the structures which are the seat of the disease process. There are two great correlating systems of the body: The chemical, which is chiefly dependent upon products from the glands of internal secretions, and the nervous system. These two systems cause the body to act as a whole instead of as many individual organs. Through them a correlation and integration of action occurs which makes it impossible for any organ to act alone.

"While the nervous system, as a whole, must be understood in order to grasp physiologic body control, it is especially important that clinicians should understand the vegetative nervous system which supplies all smooth musculature of the body, the heart, and all glandular structures; in fact, presides over the function of all important viscera. The vegetative nervous system, with the products of the glands of internal secretion, furnishes the key to the understanding of most visceral symptoms, either organic or functional.

"Upon our knowledge of these vegetative systems, we may construct a logical etiologic classification of disease of the important internal viscera:

"(1) General or constitutional symptoms. These are the symptoms that are produced by toxins, anaphylactic bodies, whatever they may be, and all products of metabolism which find their way into the blood stream. They produce general disturbances by their action upon the nervous and endocrine systems, as well as upon the body cells themselves.

"(2) Reflex, produced by efferent impulses arising from the stimuli which result from the disease and which course centralward and meditate with efferent nerves and

cause altered function in other tissues either of the same, neighboring, or remote structures; and

"(3) Those produced by disease at the seat of the lesion.

"In this classification most symptoms of visceral disease may be reduced to three causes, and by understanding that the reactivity of different individuals toward the same stimulus varies, and that the reactivity of different neurons in the same individual also varies, one can understand a fact of first importance in clinical disease—the reason for the variability of symptoms.

"If the clinician understands the general widespread action of toxins, anaphylactic bodies, and other products of metabolism, and if he further knows the innervation of the organ which is the seat of the disease process, and the neurons which may meditate with the efferent nerves which carry the stimulus centralward from that organ, he then has a basis for intelligently interpreting most of the symptoms of disease. It is still necessary, however, that he should appreciate fully that disturbed physiologic equilibrium may result just as well from psychical as from physical stimuli."

Peers, Gundrum, Howard, Johnson, and Bramhall entered into the discussion of the paper. The margin of safety, as referring to the overlapping of nerve impulses, was particularly stressed, more so in relation to the breaking down of this margin of safety in protracted disease. This was applied to certain cases of industrial accidents, and probably well explains an actual condition that we are constantly dealing with traumatic neurosis. It also was pointed out, with special regard to these reflex tracts and symptoms, that approximately 36 per cent of the digestive symptoms first entered in a patient's complaint are not due to digestive organs at all.

In concluding the discussion, Pottenger remarked that after the margin of safety has been broken down, after the pathologic stimulus has been once started, i. e., after the synapse has been passed, from that time on this stimulus goes over more easily. This, therefore, applying to compensation cases, means that we are dealing with "sick" people in their protracted stages.

The application of L. H. Sanborn was voted upon and passed by unanimous vote of twenty-eight members. First reading of the applications of J. H. Wilson and Royal deR. Baronides were read.

The report of the April meeting of the board of directors included that of the program committee. The May meeting is to be addressed by Dr. Frank P. Brendel, whose subject will be "Fractures, Their Diagnosis and Treatment," supplemented by lantern slides of cases. An evening clinical meeting is planned for June. This is to be held at the Sacramento Community Hospital. At this time, Dr. Leo P. Bell will probably present a paper dealing with the "Pre-Operative and Surgical Treatment of Splenic Anemia."

A letter from the secretary of the State Society, informing us that the May number of CALIFORNIA AND WESTERN MEDICINE will be an historical number, devoted to the history of the California Medical Association, and of the men and women who were the outstanding pioneer physicians, was received. The board considered it quite fitting to ask Dr. W. A. Briggs to prepare this subject for the Journal.

The Committee on By-Laws was not prepared to report.

~

SAN DIEGO COUNTY

San Diego County Medical Society (reported by Robert Pollock)—At the April monthly dinner of the San Diego County Medical Society, held at the Cabrillo Cafe on April 11, Charles A. Kofoid, Ph. D., addressed the meeting on the subject of "Intestinal Parasites." Dr. Kofoid handled his subject in a masterly manner, profusely illustrating his statements with lantern slides, showing the variations in the various members of the ameba family and their cysts. While his discussion was mainly upon the ameba, which he considers the chief villain in the tragedy of intestinal invalidism, he also discussed somewhat in detail the various flagellates that are found in the human intestine.

For a paper largely devoid of clinical descriptive matter, and discussing the subject mainly from the purely scientific and academic standpoints, Kofoid's presentation

was extremely interesting and held his audience spell-bound throughout. Discussion was somewhat extensively participated in by J. C. Barrow and William H. Olds of Los Angeles, and Pollock and Rees of San Diego.

Quite a representative delegation from the local society is planning to attend the Yosemite Valley meeting of the state organization. It is unfortunate that this meeting and that of the American Medical Association should run together so closely, but at this season of the year, when conventions are the order of the day, it is difficult for all to program successfully without conflict.

~

SAN FRANCISCO COUNTY

Franklin Hospital Clinical Society (reported by Ewald H. Angerman, secretary)—The regular staff meeting was held at the hospital on Monday, March 30, at 8:30 p. m., Dr. Otto Westerfeld presiding.

The program of the evening consisted of clinical discussions from J. Wilson Shields' Medical Service at the Franklin Hospital: 1. Presentation of case of sprue. 2. Presentation of case of fifth nerve palsy, accompanied by temporary amnesia—question of encephalitis. 3. Presentation of case of mediastinal syphilis. 4. Presentation of case of cerebral aneurysm, with demonstration of pathological specimen.

Cases were discussed by Naffziger, Inman, Falconer, Werner, and Yoell.

St. Joseph's Drive Success—Gastro-Enterologic Advance Urged—The recent drive of St. Joseph's Hospital of San Francisco for \$500,000 to reconstruct new fireproof units of the institution was notably successful. All elements of the community and many from afar aided in putting over the campaign—in fact, contributions are still coming in from the Sisters' appreciative friends, especially patients.

Dr. James A. Guilfoil addressed the staff on May 13 on "Advances in Gastro-Enterologic Diagnosis and Therapy," summarized as follows:

The diagnosis of gastro-intestinal disease is now a tribute to medicine. The best results are obtained because a routine examination is made that is efficient, but not too elaborate or costly. In chronic digestive disorders, a careful history is the most helpful thing, except the gross pathology disclosed by the x-ray. Periodicity of attacks suggests ulcer, chronic appendicitis or functional disorder rather than gall-bladder, for example. With a luetic history and indigestion for years, we have often cause and effect. Even a history of gonorrhea may indicate an intra-urethral chancre. Recurrent attacks of vomiting may mean migraine.

Physical examination should include throat, teeth, skin, lungs, heart, abdomen, rectum, reflexes, blood pressure, etc. An enlarged liver may be a clew to cardiac disease; irregular or sluggish pupils the key to gastric crisis of tabes. No examination is complete without a proctoscopic and sigmoidoscopic investigation. Frequently, a fissure at the base of a hemorrhoid, cryptitis, rectal cancer, or spastic sphincter ani, if treated, will relieve gastro-intestinal symptoms.

Laboratory tests enable us to make accurate diagnosis. Gastric analyses of fasting contents and after a standard meal are needed. Estimation of secretions and presence of mucus, pus, blood, bacteria, can be made only with them. Hyperacidity does not always give pylorospasm, and the latter may be simulated by achlorhydria associated with extra-gastric pathology, or even tuberculosis of lungs. Achylia may be only transitory or due to pernicious anemia, but it may be a sign of an early removable cancer. A single analysis is not always definite. Blood examinations may disclose the anemias, eosinophilia of parasites, and leucocytosis of focal infections. The urine reveals urologic pathology, producing reflex gastric or appendiceal symptoms. Stool study shows up occult blood, mucus, parasites, and fat digestions.

Roentgen-ray study is equaled by no other single method, many findings being obtained only by it, but all means must be used and conflicts studied. It requires, besides a proper technique, additional training in anatomy, physiology, and pathology. Many inferior radiograms are worthless. The best results are obtained by closest co-operation of all.

Ulcer is more accurately located by x-ray, but history

should also fit, especially with only slight deformity of bulb. Pylorospasm can be due to many lesions of abdomen, and hematemesis occurs in 5 per cent of cases of chronic appendicitis. Treatment of duodenal ulcer at the Southern Pacific Hospital, without retention, bleeding or persistent pain, is Lenhart's or Brown-Guilfoil diet, the latter having higher caloric value and avoiding loss of weight and working just as well, and bed rest. Any soft, bland diet, with frequent feedings of small amounts, is good. Routine alkalies are avoided, as patients get to depend on them for relief, instead of proper diet, which must be continued for six to twelve months. For retention of food for six hours, rest in bed and Lenhart's diet are used. If no improvement of emptying time is noted after ten days, surgery is advised. Many retentions improve with this trial. Recurrent bleeding, persistent pain, and retention of food over six hours and perforation, call for surgery.

For gastric ulcer less conservatism is used, as the percentage of medical cures is less and there is danger of malignant change. Except in young adults, without bleeding and retention, resection with gastro-enterostomy is advised. Cancer is the great baffler, and early x-ray diagnosis is disappointing, especially at the fundus and the posterior wall. Patients' lack of appreciation of slight indigestion and physicians' procrastination are also causes of not making early diagnoses.

Ptois may not interfere or may cause symptoms. Gastric polypus, diverticular processes of the stomach and duodenum are x-ray diagnoses, causing trouble rarely. Diverticulitis causes colicky pains, distention, bloating, and constipation, often followed by diarrhea after the attack. If in the sigmoid, there is desire for stool, with no result. Tenderness is felt over the lesion. In chronic diverticulitis, ulceration, adhesions, stenosis, hemorrhage, and perforation may occur and surgery is usual, but if lesions are buried in the pancreas, rest, bland diet and plenty of olive or petroleum oil are best.

Useless appendectomies are less frequent now, with x-ray study.

Multiple lesions are often demonstrated by surgeons. Appendectomy, when indicated, is done first if accompanied with uncomplicated ulcer in young adult, medical treatment being instituted. In chronic appendicitis and cholecystitis, both are operated. With cholecystitis and duodenal ulcer without gastric retention or bleeding, removal of gall-bladder has apparently caused cure of ulcer. With uncomplicated duodenal ulcer with other lesions, conservatism seems indicated and radical stomach surgery avoided if possible. "Nervous indigestion" generally indicates that a further study is needed for an organic basis.

L. B. Crow demonstrated radiograms of gastro-intestinal lesions. G. D. Schoonmaker discussed the differential diagnosis between digestive lesions and kidney-stones and ureteral stenosis. W. W. Washburn spoke of the surgical problems involved, especially in multiple lesions. Henry Kreutzmann exemplified nephritic, ureteral and duodenal plates, including diverticula. Harold Wright agreed that "nervous indigestion" generally had an organic basis, and that tabes caused visceral pain. Adolph Berg and Walter Smith stressed rectal examinations, the avoidance of multiple operations and appendiceal fluoroscopy. C. O. Southard mentioned patients cleared of nasal infection and eye-strain, with improvement of stomach symptoms.

Case histories were presented by R. F. Grant (influenza pneumonia), William Quin (gangrene of leg, coronary atheroma and lobar pneumonia), and D. E. Stafford (tubercular peritonitis).

The program for June 10 follows: "Surgical First Aid Noted in the East," Edmund Butler, discussion opened by O. E. Ekland, and "Modern Treatment of Asthmatic Conditions," S. H. Hurwitz.

Southern Pacific General Hospital Staff Holds Clinical Meeting (reported by W. T. Cummins, secretary)—The regular monthly clinical meeting was held at the hospital, Huntington Hall, Wednesday, April 1, 1925, at 8:30 p. m. W. W. Washburn presented the topic, "Other Abdominal Surgical Conditions that Simulate Kidney Lesions," summarized as follows:

Many diagnostic points were emphasized in the consideration of perinephric abscess, enlarged gall-bladder,

retroperitoneal growths, sarcoma of twelfth rib, splenic tumors, appendicitis, etc., in their differentiation from renal lesions. Retroperitoneal malignancies usually produce more intense pain and cachexia than do kidney tumors or perinephric effusions of blood or pus. The kidney is often displaced by retroperitoneal growths and intra-abdominal tumors, which may cause one to err in interpreting physical findings. An enlarged, freely movable gall-bladder may simulate a kidney. Acute unilateral hematogenous renal infection in the early stage may give no pathological urinary findings and may be confused with acute appendicitis. An illustrative case report was presented. Pathological findings in the urine in acute appendicitis may simulate a pyelitis or nephrolithiasis, especially when the appendix is adjacent to the kidney pelvis or ureter. A right-sided, acute pyelitis showing occlusion of the ureter with mucus and normal urinary findings may be mistaken for acute appendicitis. Careful history-taking, pre-operative investigation and urological studies should be carried out in doubtful cases. Hypernephroma may cause no urinary disturbance. Splenic tumors have a notched, sharp margin, and do not displace the colon anteriorly and laterally as do kidney tumors. Inflation of the colon or a roentgen picture, after a barium enema, aids in the differentiation. Case records and numerous lantern slides illustrated the subject.

Discussion—G. L. Eaton, with chart and roentgen pictures; W. I. Terry, L. B. Crowe, M. P. Burnham, P. K. Brown, O. E. Eklund, and F. A. Lowe.

St. Luke's Clinical Club—The regular meeting of St. Luke's Clinical Club was held Thursday, April 23. H. A. L. Ryfkogel presented the subject of "Splanchnic Anesthesia." This method of anesthesia is much more popular in the East than here. The speaker himself has had very good results with a modified Cappus method, using one-half per cent of novocaine instead of the 1 per cent recommended by Cappus. He had found 1 per cent dangerous. This method is especially good in old people, who cannot stand the ordinary form of anesthesia. It is absolutely devoid of shock. Splanchnic is the method of regional anesthesia. Blocking of the two major splanchnic nerves is preferable to the paravertebral method. Finster, who has done a good deal of this work, has had a very low mortality. Again, we do not have the same mortality from pulmonary complications. The field block in the abdominal wall is the method of choice. If you are going to use this method, inject regionally before you block off your main splanchnic nerve.

The subject was further discussed by Dr. Rosberg, who dwelt on the work done by the Mayo Clinic, and who brought up the question of a more general use of other anesthetics, such as ethylene gas.

St. Mary's Hospital Clinical Society (reported by Randolph G. Flood, secretary)—The regular staff meeting was held Friday evening, May 1, Dr. R. Topham presiding.

An interesting paper, accompanied by slides and patients, was presented by H. Spiro, subject: "Aneurysms of Thoracic Aorta." Among the more important points brought out by Spiro, was the differential diagnosis of diffuse dilation and aneurysm of the thoracic aorta. Of primary aid in the differentiation is the radiographic plate, taken with the patient in the right oblique position, which throws into marked relief any irregularity of any part of the aorta. This paper was discussed by Drs. Morris, Monica Donovan, and Edmund Butler.

✽

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by Alex C. Soper, Jr., Secretary)—The May meeting of the society was a special one held at Lompoc, with the scientific program arranged by the physicians of the northern part of the county, and a complimentary dinner given by the Lompoc Chamber of Commerce, after several hours, during which they conducted members of the society about their beautiful valley. The chief point of interest was, of course, the works of the Celite Products Company, where mountains of "diatomaceous" chalk compound are being cut into for various commercial products, and sent all over the American continent and to Europe. Covering about 2000 acres, and extending to a known

depth of 1500 feet, this company employs and houses about 600 men, and has a well-equipped hospital and houses, and so forth, for its men.

The medical meeting was held at the American Legion hall, and was called to order at 9 p. m., President Nuzum in the chair. Owing to the lateness of the hour, and the long distance from Santa Barbara, no routine business was transacted, except a unanimous vote to endorse and support the formation in the county of a branch of the American Association for Medical Progress, starting under the auspices of Mr. George E. Coleman, the Santa Barbara bacteriologist.

Twenty-nine members were present, and the following guests: Dr. Bracken, former State Health Officer of Minnesota; Dr. Harris, Santa Barbara County Health Officer; Dr. Schwartz of Lompoc, Dr. Schultz and Dr. Blaisdell of Santa Paula.

Program—"New Method of Treatment of Eclampsia," Lysle McNeile, Los Angeles.

"Fungus Diseases of Human Beings," Roy Hammack, Los Angeles.

"Treatment of Abortion," W. D. Sink, Guadalupe.

"Five Cases of Acute Osteomyelitis," M. Thorner, Santa Maria.

Discussion of papers was held by Sansum, Spaulding, Sink, Pierce, Profant, Cummings, Ullmann, Eaton, Nuzum.

SONOMA COUNTY

Sonoma County Medical Society (reported by G. A. Hunt, secretary)—The Sonoma County Medical Society met in Santa Rosa Thursday, April 9. Eighteen members were present. The speaker of the evening was Dr. Emmet Rixford, who gave an address on "Ulcer of the Duodenum and Stomach." The entire evening was given to the discussion of this subject, and members who came many miles to the meeting considered themselves well paid.

TULARE COUNTY

Tulare County Medical Society (reported by John C. Paine, secretary)—The society accepted invitation of Dr. D. D. Nice of Three Rivers to dine with him and hold their monthly meeting at his beautiful ranch house, April 26.

Members present were Drs. Willey, McSwain, Fraser, Tourtillott, Melvin, Brigham, Nice, Preston, Edmonds, Betts, Seligman, Campbell, Zeller, Ginsburg, Tillotson, Todd, Lipson and Paine, with Drs. Hill and Furness as guests, in addition to Dr. J. H. Woolsey of San Francisco, the speaker of the day, and Dr. Fred De Lappe of Modesto, councilor of the district.

After a very bountiful repast, the members listened to an interesting talk by Dr. De Lappe in his capacity as councilor of the district, which contained much interesting information and was appreciated by all. Dr. Woolsey then gave a forty-five-minute talk on the "Treatment of Infections," which was enthusiastically received.

CHANGES IN MEMBERSHIP

New Members—Alameda County: David E. Froelich, Ben Stetson, Oakland; A. J. Howell, Berkeley.

Kern County—Lucille B. May, Bakersfield.

Los Angeles County—Edwin S. Budge, Robert A. Campbell, Elmer J. Lambert, J. S. McAtee, George H. Patterson, J. W. Pidcock, Warren Sheley, Pinne M. Welbourn, Louis Levin, Los Angeles.

Napa County—Harry V. Baker, George B. Todd, Napa; E. F. Donnelly, Imola.

San Benito County—Sanford W. Cartwright, Idria.

San Diego County—Julio Paez, William H. Wilson, San Diego; William R. Eastman, La Jolla.

San Francisco County—John R. O'Neill, Arthur Sonnenberg, Eugene M. McKevitt, J. Morrille George, Myrnie Ada Gifford, Alexander David McLean, San Francisco.

San Luis Obispo County—John W. Nielsen, San Luis Obispo.

Santa Barbara County—Horace Gray, Horace Hagen, Kent R. Wilson, Santa Barbara.

Transferred Members—Hans B. Christiansen, from Alameda County to San Francisco County; Lloyd A.

Clary, from Contra Costa County to San Francisco County.

Resigned—C. E. Locke, Jr., H. H. Whitner, San Francisco County.

Deaths—Foye, Frank Alonzo. Died at Eagle Rock, April 28, 1925, age 44. Graduate of the College of Physicians and Surgeons of Los Angeles, 1912. Licensed in California the same year. Doctor Foye was a member of the Los Angeles County Medical Society, the California Medical Association, and the American Medical Association.

CORRECTION

It is pleasant to be able to correct an error that appeared in the Obituary column of the April Journal. The Orange County Medical Society lost one of their most active members, W. Leland Mitchell, M. D., not by death, as was erroneously published, but by reason of his removal to France, in connection with the Rockefeller Foundation.

CALIFORNIA ASSOCIATION OF PHYSIOTHERAPISTS

(Reported by B. H. Stenvig, secretary San Francisco branch)

The subject of the April meeting of the San Francisco branch of the California Association of Physiotherapists, held at St. Luke's Hospital, was nervous disorders and their treatment.

R. W. Harvey, M. D., spoke on the various nerve conditions and their treatment from a physiotherapy standpoint, stressing the use of hydrotherapy. He divided nervous disorders into the two classes of organic and functional. The organic class includes the spastic and flaccid types of paralysis, in both of which he advised the use of light massage after the first stage of soreness has worn off. The benefits of this form of treatment are twofold, the physical benefit in keeping up the nutrition of the affected parts and preventing deformities, and the psychological in keeping up the morale of the patient in his feeling that something is being done for him.

In the functional class he spoke of neurasthenia and hysteria. As a usual thing in neurasthenia some organic cause can be found and measures taken to remove the cause. The symptoms are headaches and a feeling of fullness in the back of the head and the eyes. Often there is some stomach trouble; the patient is easily tired; almost always insomnia exists, the muscles are tense, and the patient is continually fearing something that never happens. One of the first things to try to gain in the patient is relaxation. This can often best be gained by a course of warm tub baths and massage, the time of the bath and the temperature being regulated. At the same time other hygienic measures, such as diet, are taken. With few exceptions Dr. Harvey finds there is an improvement within two or three weeks.

Hysteria presents an entirely different case in that usually no organic cause can be found. Often some shock in childhood or certain environments act as trauma. With adults, excesses of various kinds will cause hysterical psychosis. In some cases the same treatment is successful in improving the condition, although this type is very much harder to treat.

Following Dr. Harvey's talk the meeting adjourned to the Physiotherapy Department at St. Luke's, where the technician in charge gave a short demonstration in hydrotherapy. For the baths which Dr. Harvey spoke of, the hammock or continuous bath, as it is sometimes called, is most effective. This is a tub with a canvas hammock slung in the tub in which the patient may rest. There is a rheostat for controlling the temperature of the water, it being possible to keep the same temperature for hours at a time if necessary. For the ordinary neurasthenic type the usual time is fifteen or twenty minutes at a temperature of 98 degrees or 100 degrees Fahrenheit. Maniacal patients are sometimes kept in for an hour or several hours, the purpose of the bath being to insure enough relaxation so that the patient can sleep.

Utah State Medical Association

 J. U. GIESY, Kearns Building, Salt Lake City,
 Associate Editor for Utah

GET TOGETHER

One of the high lights of the medical month was the banquet extended by the Salt Lake County Dental Society to the Salt Lake Medical Society at the Elks' Club on the night of May 4.

Not only was this a pleasant occasion from the standpoint of individual enjoyment, of good music, good entertainment and good food, but in its deeper indications of a friendly spirit existing between the two groups of that "get-together" spirit which more than anything else in life helps us to understand and appreciate one another in a sympathetic fashion.

We don't mean that either the dentists or doctors need sympathy either. That's not the point we're trying to reach. What we mean is that understanding, acquaintance with a man, his aims, objects, character, enable us to evaluate him and them in the truest sense. And the thing is true of nations as well as men. Many a man we do not like any too well we would find to be a pretty good scout if we knew him better, knew him as he really was, instead of forming our opinion of him snapshot.

And so these meetings, these broadening of acquaintance, these establishments of friendly relations are steps in the right direction. We're sure that every doctor who attended enjoyed the banquet. And surely it was a graceful gesture on the part of the dentists to furnish us food to eat after laboring to save our teeth. Anyway mouth conditions are a very important factor from the cradle to the grave.

WHA'SA MATTER, DOC?

It has been reported that in China a doctor is paid so long as his patient remains healthy and works without remuneration when he falls sick. I have heard this statement evoke laughter. But, what's funny about it. The Chinaman is not necessarily crazy because he does things differently from us. After all, what is the Chinaman doing but maintaining a prepaid insurance guaranteeing him medical attention when ill?

And we know all about insurance. We carry sick and accident policies, income insurance, and life. We insure ourselves against accident or sickness when neither sick nor hurt. We insure ourselves and our dependents against poverty or destitution when we are neither poor nor destitute. We insure against burglary before we have been burglarized. We insure our lives. And insurance is, after all, a gamble. The carrier bets that we won't be sick or hurt, or robbed, or incapacitated, or that we will live an average number of years, and we bet that we will or won't—and to win we have to lose.

Yet insurance is an excellent thing. It has mitigated a world of suffering and sorrow, and done much good. We're for it. We're for it so strong

we would carry it further. Why not a sort of longevity insurance, or a thing that amounts to as much. How many men and women die a needlessly early death because of unsuspected, or neglected conditions which might have been retarded or cured if taken early enough?

Tire agencies offer free inspection service to help us avoid road accidents and, of course, to sell their goods. Battery agencies give battery inspection to help us get the most out of the little old box. About every so often we have our engines overhauled, inspected, and tuned. Fair enough.

But what about ourselves—the engine that makes the very difference to us between life and death—our bodies—their health. What if we, as physicians, would take a leaf from the book of the Chinese—what if we would educate our patients along the lines of a "physical inspection" as a means of keeping in condition before they are actually taken ill or faced by death itself?

We believe in prophylaxis, preach it, practice it in vaccination, immunization, quarantine. We believe that an ounce of prevention is worth the proverbial pound of cure. And yet we go on from year to year failing to emphasize the importance of the widest prophylactic field. Prophylaxis means prevention, and how better prevent a thing than discover it in its incipiency and abate it.

What, then, if as a step in this direction we, as physicians, should begin to educate our patients to come in about every so often, whether feeling in need of professional attention or not, and simply say, "Wha'sa matter, Doc?" Then give him an overhauling—learn whether there is anything the matter or not. If the answer is negative, well and good. The man goes away satisfied in the knowledge that he is in a good condition, actually buoyed and strengthened by the fact. But if there is really something the matter, then overhaul the engine at once, even though the trouble is but the smallest, faintest knock. Here is a real service physicians might and may yet render to their race. And surely it should be worth as much to a man to know that his teeth, his heart, his lungs, kidneys, liver or what not are in good condition as to be informed by a smiling mechanic that "the old boat is now hitting on all six."

In these days, when we are trying by lectures, written word, and radio to educate the public, why not educate them in the prevention of individual affliction insofar as we may, as well as in the present methods of attack and cure of disease? Why not seek to stress the fact that in this age, when as never before means of examination and diagnosis are at the disposal of the average physician—one of the wisest acts they can perform—one of the cheapest forms of insurance they can purchase—may both be attained by simply now and then going to their medical adviser's office, and, having gracefully and smilingly saluted the young lady office attendant, stroll on into the sanctum sanctorum and accost its occupant in some such fashion: "Good morning. Look me over and tell me wha'sa matter, Doc."

Utah News Notes (reported by J. U. Giesy, associate editor for Utah)—The officers of the Utah State Medical

Association met the members of the Boxelder Medical Association at a luncheon at the Commercial Club in Brigham. The visiting doctors were Sol G. Kahn, president; William L. Rich, secretary; J. C. Landenberger, counselor; W. D. Calderwood. Following the luncheon, the members of the state and local associations motored to Logan, where a scientific program was given by Dr. Calderwood. The officers of the Utah State Medical Association also visited the Utah County Society meeting at Provo, the Weber County Society at Ogden, and the Boxelder Society at Brigham City during the month. F. Steele delivered the scientific paper at Provo, and J. C. Landenberger at Ogden. Rich and Kahn spoke at Brigham City.

Salt Lake County physicians were the guests of the Salt Lake County dentists at the third annual dinner of the Salt Lake County Dental and Medical Societies held at the Elks' clubhouse. About 250 members of both societies were present.

The Holy Cross Clinical Association met at the hospital on the evening of April 20. The program was as follows: Gas Bacillus Infection, John Sugden; Intermittent Hydronephrosis, W. G. Schulte; Carcinoma of the Rectum, C. L. Shields.

Salt Lake County Medical Society (reported by M. M. Critchlow, secretary)—At the meeting of April 27, S. C. Baldwin presented a boy treated for lymphosarcoma of the neck four years ago, with a recent recurrence of cervical adenitis, and discussed the differential diagnosis. A. A. Kerr outlined the clinical history of a case of suppurating orchitis and epididymitis, and presented the pathological specimen.

The society was fortunate in having Emil Novak of the Department of Gynecology, Johns Hopkins University talk on "Uterine Bleeding." He divided the causes into three groups: First, those in which the bleeding is caused by a lesion in the pelvis; second, those in which the lesion is inflammatory, but not enough to cause bleeding itself; third, those in which there is bleeding in the absence of disease in the pelvis. The lecture was well illustrated by lantern slides.

W. R. Calderwood, E. F. Root, Ezra Rich of Ogden, William L. Rich, A. A. Kerr, and T. F. H. Morton took part in the discussion. In closing, Novak analyzed thoroughly the treatment of hyperplasia of the endometrium by curettage, x-ray and radium, and organotherapy.

President Brown announced that comparatively few doctors are taking advantage of the parking privilege extended by the police for the fee of \$5.

W. R. Calderwood reported for the committee to supervise public lectures.

Radio Broadcasting—President John Z. Brown of the Salt Lake County Medical Society has appointed a committee to supervise public health lectures. This committee has arranged for members speaking in the name of the society to broadcast a health talk over the radio once a week. These talks have been broadcasted for several weeks and have proved to be very popular.

Simple Immediate Treatment for Vomiting—All patients suffering from symptoms of reverse peristalsis in the upper gastro-intestinal tract from various causes were given amounts of 2 per cent sodium chlorid solution varying from 50 to 200 cc. In every case there was immediate relief of symptoms, but in several cases the relief was transient. Edwin P. Lehman and Harry V. Gibson, St. Louis (Journal A. M. A.), suggest the possibility that the action is a local one, tending to establish forward peristalsis in the stomach, no matter what the cause of the reversal. It may be found that the expression of this effect in amelioration of symptoms depends on the intensity of the abnormal stimuli to reversal of peristalsis. The treatment is so simple and harmless that it deserves a trial by clinicians everywhere, with a view to confirming or disproving these observations.

If every potential mother would keep herself in suitable condition for successful pregnancy and triumphant motherhood, there would be more normal births and fewer sick and dying babies—a larger number of healthy mothers.—Ida Bailey Allen (Medical Review of Reviews).

Nevada State Medical Association

W. M. EDWARDS, M. D., Mason.....President
CLAUDE E. PIERSALL, M. D., Reno.....
Secretary-Treasurer and Associate Editor for Nevada

The 1925 Session of the Nevada Medical Association—The 1925 meeting of the Nevada State Medical Association will be held at the Elko General Hospital, Friday and Saturday, September 4 and 5, reports C. E. Piersall, secretary.

It has been announced to a number on our program that it would be September 11 and 12, but the dates are changed so that our program will not conflict with the Utah State Medical meeting and post-graduate course, which will be held September 7 to 12, inclusive.

Friday, September 4, we will have a luncheon at the General Hospital, and Friday evening at the theater a movie on pulmonary tuberculosis. Saturday evening we will have a real banquet at La Moille, such as we had there in 1921. Saturday will be devoted not only to papers, but to clinical demonstrations. Sunday, September 6, we will have a fishing trip, which the Elko County Society maintains may be the best that can be had anywhere in the United States.

The following is a quotation, in part, of Dr. W. A. Shaw's letter to the secretary, dated April 25, 1925: "We intend to have the finest meeting that has ever been put over in the state of Nevada. We put over a meeting in 1921 that we figured could be equaled, but not excelled. Reno apparently excelled our meeting at Bower's Mansion in numbers only. We, in Elko County, shall put on a meeting in September which will be written in the history of the Nevada Association and which will also be remembered enthusiastically by all the medical men who attend."

Our Nevada members are urged to present clinical cases, to write to your secretary for a tentative program, then decide what subject you will present or discuss. All members and visitors who are to present a paper or clinical demonstration are urged to send to the secretary a resumé of their subject as early as possible, so that those listed for discussion may be prepared for the same.

The Elko Society will provide space for exhibitors.

The Washoe County Medical Society, according to the report of Henry Albert, secretary, met in regular session at the Chamber of Commerce, April 12, President Vinton A. Muller presiding.

The minutes of the previous meeting of April 13, 1925, were read and approved.

Program—Dr. Carl L. Hoag of San Francisco addressed the society on "The Acute Abdomen." He divided the acute abdominal conditions into two large groups, namely: Those which are inflammatory from the beginning as, appendicitis, cholecystitis, etc., and second, those which are primarily traumatic and only secondarily infectious, as gunshot wounds, perforation of gastric ulcer, acute intestinal obstruction, etc. The following list of symptoms were discussed in detail, as they pertained to the two great groups in question: Onset (especially pain), chill, temperature, tenderness, vomiting, rigidity, flatus.

Paper was discussed by Brown, Albert, and Piersall.

Attendance—Members: Adams, Albert, Bath, Brown, Muller, Pickard, Piersall, Riley, Robison, Tees, Thompson, and Walker; also, Dr. Lehnars of Reno, Mrs. Hoag of San Francisco, and Mrs. Muller of Reno.

The brain is the organ of thought, just as the stomach is the organ of digestion. It handles perceptions just as the stomach handles food, and is subject to all the physical laws which control the rest of the body. The brain must be exercised and thus given the zest of wholesome employment.—Chicago's Health Bulletin.

ANOTHER POPE TRAVELOGUE

Nairobi, April 10, 1925.

My dear Dr. Musgrave—Though we have not entered the game fields of Africa, I thought I should report progress.

Our transatlantic trip was surprisingly pleasant and smooth. Our five days in France entitle us to write a book on "What We Think of the French." Paris, naturally, interested us very little, and we passed through with nothing more than a deferential salute to her beauties.

Marseilles was a much more picturesque and villainous town. I never saw such a collection of strange and murderous-looking people as those on the waterfront—the dregs of the Mediterranean fit for deeds that are dark.

We liked the town and its surroundings the best of all France, and toured Provence with great pleasure.

Our voyage on the Mediterranean was the roughest we encountered, the sky being far from the sunny heavens one sees on the postcard. The paradox continued, fortunately, and the Red Sea and Gulf of Aden we found cool and delightful. This is usually the hottest sea journey that one can make. After seventeen days on the General Duchesne we appeared off the coast of Africa and experienced what had always seemed to me to be a figure of speech. We smelled the spice-laden winds of Africa. The low palm-rimmed beaches were actually fragrant at a distance of several miles. It was like unrolling a Chinese matting in which incense had been packed.

The town of Mourbasa, where we landed, is an old Portuguese settlement many hundreds of years old. Its name means: the Island of Wars, and the old fortifications of Vasco Da Gama still guard the port.

Here we got the true color of the Occident. Somali, Swahili, Arabs, and a few British inhabit this amazing town. The children of the jungle, with all their fine primitive qualities, meet modern material culture as represented in Henry Ford's marvelous Kinetic apparatus. Wild-eyed Shenzi, from the bush, gaze with awe at the magic of the white man, but lose none of their dignity and noble bearing.

From Mombasa we traveled by rail to Nairobi, a trip of three hundred miles. Now we are outfitted and ready to start in the morning for Tanganyika. In three days we shall be lulled to sleep by the coughing grunt of the night-roving lions and the tittering wail of hyenas.

Leslie Simson received us here, and we already have our tent boys, gun-bearers, and provisions ready to start. The gun-bearers were somewhat reluctant to join us, till they saw our archery tackle and saw us shoot. Now we have them squatting on the veranda before us, sharpening arrows, enthusiastic to go.

Simson states very emphatically that we shall have every opportunity to come in contact with a large variety of game, including the king of beasts, and he has no qualms as to the outcome.

You shall hear of this soon.

Yours as ever,

SAXTON POPE.

Our Obsessions—Dean Johnston of the University of Minnesota says: "The greatest American obsession is the habit of going to school. A second great American obsession is the belief in equality. . . . The dogma appeared in the first sentence of our Declaration of Independence, 'All men are created equal.' *No American patriot believed that for a moment.* The instinct for sameness has played a prominent part in the development of our educational institutions. . . . The Chinese bind their girl's feet; we bind the whole child, body and soul. A third great obsession of our nation is the belief that the good things of life can be given to people. Parents fondly hope that they can give their children an education. This is quite impossible; as it is almost equally impossible to keep worthwhile young people from getting an education for themselves. We advise children to prepare themselves for law, medicine, engineering, dentistry, business—with a capital B—and for everything except the work that needs to be done."—*Journal-Lancet*.

California Board of Medical Examiners

SOME PROBLEMS AND ACTIVITIES OF THE BOARD OF MEDICAL EXAMINERS

(Reported by C. B. Pinkham, M. D., Secretary)

Report from Los Angeles states that on April 8, 1925, Seth M. Wells and James M. Fer Don were convicted of fraud in an oil promotion scheme and sentenced by U. S. Judge Paul J. McCormick to pay a fine of \$1000 and serve one year in the Los Angeles county jail on each of two counts. Stay of execution was granted for thirty days to enable defendants' attorneys to prepare for filing an appeal.

The minutes of the Board of Medical Examiners disclose Seth M. Wells some years ago operated a traveling medicine show in California and elsewhere. His application for a license to practice in this state, based on reciprocity with Iowa, was denied at the February, 1924, meeting of the board after an extended hearing wherein his professional record was fully discussed.

It is reported that Francis D. Coltrin, M. D. of Fullerton, was arrested April 13, 1925, by U. S. Federal Narcotic Agent V. H. DeSpain for violation of the Harrison Narcotic Act, he having been alleged to have sold twenty to twenty-five grains of morphine to an addict operator, who paid him \$25 in marked money. At the hearing of Dr. Coltrin before U. S. Commissioner Turney on April 14, 1925, he was held to answer under \$5000 bond. At that time he testified he had given morphine to the addict, who stated he wanted it to enable him to make a trip to Texas; that he did not charge the addict, but the addict wanted to give him \$25, and when refused said addict left the money on the doctor's table.

Skigerosky Adachi, alleged to have been in business in Los Angeles for some time, ostensibly manufacturing handkerchiefs, was recently found to have displayed on the wall of his reception room an imposing diploma, conferring upon him the degree "Doctor of Bacteriology," said diploma being issued by the "International Physician and Surgeons' College of Micro-biology," dated Chicago, Illinois, February 2, 1925, and signed T. D. Hyland, M. D., president; P. Tempone, M. D., secretary.

"Dr." John F. Costa, Lemoore, California, was recently held to answer in the Superior Court on a charge of having practiced medicine without a license, it being alleged that John R. Mendez was prescribed for by defendant and, instead of recovering from his malady, became worse and eventually insane, so that he was committed to a state hospital. "Dr." Costa is reported to be at liberty on a bond of \$5000.

Reports relate the arrest of George A. Bruning and H. C. Coulson, naprapaths of Los Angeles, on a charge of violation of the Medical Practice Act. It is related that they belong to a national association which will pay their fines, attorney's fees, etc., and that an attempt will be made by some twelve or thirteen naprapaths, now located in California, to obtain a separate board of examiners.

The theory of the naprapath is that various ailments are due to pressure on nerves, caused by tight ligaments in the spinal column, said theory being originated by Oakley Smith, who operates the Chicago College of Naprapathy, Chicago, Illinois.

R. H. W. Albrectondare, who not long since was convicted of violation of the Medical Practice Act in Santa Ana, California, following the death of two women patients, lost his appeal to the District Court of Appeals for a new trial; however, he has petitioned the Supreme Court for a hearing, and we understand the matter must be disposed of before April 19, 1925.

Dr. Albrectondare, who so far as can be ascertained has never studied medicine or any other system of treating human ailments, was given considerable newspaper notoriety about a year ago in connection with his troubles in Pasadena and Orange.

The San Francisco Chronicle of April 18, 1925, relates

that Wilbert LeRoy Cosper, self-styled bishop of an Oakland religious cult, was found guilty on April 17 in the Superior Court at Martinez of violation of the Medical Practice Act, but did not seem to be annoyed by the verdict and is quoted as having stated, "What is a fine of a few hundred dollars when one has been given a million dollars worth of publicity?" Cosper was charged with having held a clinic in the home of a Mrs. Dietrich, Richmond, California, who was about to become a mother. It is reported that "Dr." Cosper, with a number of students, made such a commotion in the home of Mrs. Dietrich that the husband is charged to have shouted, "Get out, you dirty dogs."

Cosper formerly had an office in the Pacific Building, San Francisco, when complaints were filed that he was alleged to charge a fee for treatment, which was reported to consist in his sitting before his patient with his eyes closed for a few minutes, and then a request that the patient return again at a certain time for another treatment.

Some years ago Cosper was also in considerable financial difficulty over a moving picture which he filmed and had produced at the Savoy Theatre, entitled "The Kingdom of Human Hearts." Shortly after the film was completed, his producer, J. Patrick Kennedy, called at the office of the Board of Medical Examiners, leaving a "certificate of ordination," which he stated Cosper had given him, said certificate conferring upon Kennedy the degree D.D. and C.P., certifying that Kennedy had been ordained a priest of the Christian Philosophical Church, and thereby was entitled to treat by prayer the sick and afflicted. At another time he created considerable publicity by staging a boxing bout in the pulpit of his church in Oakland.

It was reported that last year he was involved in other financial difficulties arising from an attempt of "several feminine followers to get back certain funds which they had advanced on notes to Cosper for the advancement of his cult."

The Sacramento Bee of April 15, 1925, relates that Dr. Earl Harlan of Colusa, a physician and surgeon, had been indicted by the federal grand jury on a charge of possession and sale of narcotics.

On March 17, 1925, Allen Mills, Chirothesian, Richfield, Tehama County, California, was charged with violation of Section 17 of the Medical Practice Act. According to the report of our investigator, Mills stated that he made "a positive diagnosis by the examination of the pulse, by examination of other parts of the person of the patient, and by what the defendant termed iridiagnosis."

Mills claims to be an ordained minister of the "Chirothesian Church of Faith, incorporated under the laws of California, August 2, 1917." In "The Chirothesian," a pamphlet published by the organization, it is related: "It is intended by the board of trustees of the church that the word 'Chirothesian' shall have as much significance as that of minister of an orthodox church or as *even that of 'M.D.'* * after any person's name." The pamphlet further relates that, although the original papers of incorporation were issued under the title "Church of Faith," later the word "Chirothesian" was adopted "by the board of trustees as the title under which the ordained ministers of the church should advertise and practice their healing work . . . and while working under this title, healers ordained to the work are *protected from annoyance by the State Medical Board.*" *

M. T. Larkin, a Chirothesian of Los Angeles, was charged with violation of the Medical Practice Act of January, 1925, and at the time of investigation his place of business is reported to have contained a large quantity of remedies, the bottles being labeled for various diseases, such as tumors, rheumatism, paralysis, cancer, etc. On his wall was a diploma from the Western College of Drugless Therapeutics and, according to information from the Department of Licenses, State of Washington, a letter from the Sanipractic Board of that state relates that the Western College of Drugless Therapeutics was a "fly-by-night" affair "apparently for the purpose of giving a few persons a sort of diploma."

Our investigator further reported that on the wall of

Chirothesian Larkin's office was a sign reading, "We diagnose your ailments if you wish us to do so." Larkin, in answer to the question of our special agent as to how much his certificate of membership in the Chirothesian Church had cost him, is reported to have replied: "It cost me about \$250 so far. I paid \$75 at first, and as I don't go to church very often, I sent them \$5 or \$10 occasionally."

Diploma Mill Indictments—Replying to a letter of inquiry from the Board of Medical Examiners with reference to this subject, Mr. I. M. Golden, assistant district attorney of San Francisco, writes:

"I beg to advise you that the cases have been dismissed upon the ground that the authorities of San Francisco have not given to the district attorney the needed funds with which to prosecute, to extradite witnesses, and to transport witnesses from other states to California. The record is clear that the district attorney and the Board of Medical Examiners did all that was humanly possible to bring the cases to trial."

Surely this is sufficiently illuminating without additional comment.

"Bishop" Cosper Given Ninety Days—"Bishop" Wilbert LeRoy Cosper, leader of the Christian Philosophical Institute of Oakland, and self-styled "apostle of the divine chemist," was sentenced recently by Superior Judge H. V. Alvarado in Martinez to ninety days in the county jail and a fine of \$500 for violating the Medical Practice Act.

CALIFORNIA AND WESTERN MEDICINE discussed the "Bishop" and his alleged Philosophical Institute when the propaganda was at its height last year.

According to press dispatches an attempt may now be made by the Contra Costa followers of the convicted "Bishop," who, he says, number 1100, to recall Superior Judge Alvarado.

When Cults Are Forgotten—An isolated community of one thousand people had one physician. The data are not now available as to the number of spinal manipulators, testimonial shooters, drugless healers, nature friends, and what not shared the care of the community during relatively healthy times. We do know that when an emergency arose, when the results of the knowledge of the regular school of medical practitioners and those in other allied fields who have been so bitterly assailed and maligned by the opponents of medicine was needed, the whole world sat at its doorstep to watch through the press, to listen by the air, to compute on its maps, the trip against death. A small package was visualized by millions. Worthless glass vials assumed unheard of value because of their life-giving contents. Forgotten the vaunted merits of subluxation of vertebrae for nerves which never reach the spinal column. Disregarded the tenets of absent treatment. Water cures, mud cures, ice cures, are not mentioned.—Herman Goodman, M. D.

"What are the attractions of a career in life?" asks Doctor William Henry Welch, who then proceeds to answer by saying: "They lie, do they not, in the opportunities the career offers for service to mankind, in the congeniality of the work and in its rewards. The profession of medicine surpasses all others in its opportunities for service to our fellow-men. Besides this there are manifold fields of activity, appealing to the most varied personal inclinations and aptitudes, be these practical or scientific. The rewards of success in medicine, even of the highest success, lie not in money; they lie in the intellectual pleasure which one gets from his work as a physician, in the consciousness of service, in the relief of suffering, and in the cure and prevention of disease." Doctor Welch has just celebrated his seventy-fifth birthday, and so far as we have seen he has not told the newspapers how he managed it. In fact, Doctor Welch is partial to scientific journals for such messages as he has to give.

*Italics ours.—Editor.

Clinical Notes and Case Reports

ADENOMYOMA, WITH THE INFILTRATIVE CHARACTERISTICS OF MALIGNANCY

By H. E. BUTKA, M. D., *Los Angeles*

The usual finding of adenomyomata is in the wall of the uterus with rather indefinite outline and with color almost that of the normal uterine wall. The finding of adenomyomata elsewhere is rather unusual. The case here presented is still more unusual in its relation to the surrounding organs.

No. 13485—White Memorial Hospital—Service of Dr. Thomason—Mrs. C. C., age 38 years; housewife. History of profuse menstrual flow for a few days and then scanty but continuous flow of four months' duration. Physical examination revealed perineum and cervix intact. Body of uterus quite firmly fixed and about 5 cm. in diameter, with a nodule apparently involving posterior wall of uterus and rectum. Laboratory findings revealed 10,200 leucocytes, $3\frac{1}{4}$ million red cells with 75 per cent of polynuclears. Wassermann, negative.

At operation three small fibroid nodules were found in the body of the uterus. One ovarian cyst measuring 5 cm. in diameter was present. Anterior to the uterus, between it and bladder and adhered to both is found a tumor mass measuring about 3 cm. x 5 or 6 cm. in size. This mass could be separated from the uterine wall, but it was found impossible to separate from the bladder wall, and necessitated the removal of the adherent portion of the bladder with the mass.

A similar nodule adherent to the rectum posterior to the uterus was found. It was impossible to remove this mass without removal of a portion of the rectal wall, and with the extensive surgery already completed it was thought best to leave this tumor mass for the present.

Pathological study reveals tumor anterior to uterus and adjacent to bladder wall to consist of a typical adenomyoma, small areas of stroma with glands of type found in endometrium. No evidence of malignancy found. The tumor mass invades bladder wall, leaving only traces of bladder muscle and the mucosa in involved area.

Other findings were: peritoneal and parovarian cysts, cyst of ovary, fibroids (small in size and three in number), and a chronic catarrhal inflammation of the appendix, with the endometrium in the resting stage.

Comment—Rapid section, using Terry's polychrome methylene blue, revealed the nature of this growth, and although the gross appearance suggested malignancy, more radical surgery was not done. Patient has recovered.

BISMUTH SUBNITRATE POISONING

REPORT OF A CASE

By C. W. PIERCE, M. D., *Los Angeles*

There is a more or less prevailing view that bismuth subnitrate may be used with great freedom, both externally and internally, regardless of the fact that our attention has been repeatedly called to its danger. That the matter may again be brought to the attention of physicians, I wish to report the following case of bismuth poisoning:

Mrs. C., age 31, was admitted to the California Lutheran Hospital, September 19, 1924. Four months previously a tuberculous kidney had been removed by Doctor Franklin Farman. A fistula formed and persisted. Squibbs' 33 per cent bismuth subnitrate was used in the wound. Altogether during one month four ounces were used. The patient lived in the country and was not kept under close observation.

Three months after the operation she developed signs of salivation. Sloughing ulcers appeared in the mouth and blood was noticed in the urine. She consulted a den-

tist and was also treated by her local physician without the cause of the trouble being discovered.

The patient entered the hospital complaining of intense pyralism, pains in the face, headache, abdominal pains, vomiting, diarrhea and hematuria. She was very weak and had lost several pounds in weight. The breath was extremely offensive, so much so that the odor could be noticed on entering the room, simulating a garlic odor. The pains in the face were severe. Examination showed a black or slate discoloration of the edges of the gums, the mucosa of the cheeks and lower edge of the tip of tongue. Severe stomatitis and gingivitis. Some of the ulcers were quite deep, penetrating to the deeper layers. Urinalysis showed granular and hyalin casts, pus and red blood cells.

Treatment consisted of daily injections of a 10 per cent solution of sodium thiosulphate, intravenously. Each dose contained ten cubic centimeters of the solution, and a total of four injections was given. A mouth wash was used to heal the gums. One loose tooth was extracted. The acute nephritis which had developed as a sequela of the bismuth poisoning began to subside immediately under the above treatment, and at the time of her dismissal from the hospital the kidney function was normal. Her mouth healed and general condition improved. The dark line under the tongue and discoloration of the mucosa of the cheek persisted and was still present a month after she left the hospital.

1501 South Grand Avenue.

Medicine Before the Bench

Findings and Comments of the Courts on Acts and Omissions of Doctors

(EDITOR'S NOTE—*The law reports contain many interesting decisions, involving the reputations and fortunes of doctors. In this column in each issue a brief summary of one or more decisions and comments of the several courts of last resort upon the cases will appear. The matter will be selected by our general counsel, Hartley F. Peart, who, with Hubert T. Morrow, attorney for Southern California, will contribute from time to time.*)

In the most recent malpractice decision decided by our Appellate Court the importance of expert medical testimony to prove negligence on the part of a physician was emphasized. The judge before whom the case was tried instructed the jury that the opinions of the doctors who had testified as experts were merely advisory and that the jury was not bound to accept such opinions as true, but should accord them such weight as the circumstances warranted, or the jury might disregard such opinions entirely if they believed them to be unreasonable. The court held that this instruction was erroneous as, in effect, it instructed and permitted the jury to set up their own standard of treatment which they thought the physician should have given the case and permitted them to entirely ignore the expert testimony. The physician was charged with negligently failing to discover a fracture by reason of the fact that he took no x-rays. Two physicians testified that this was negligence. The court said:

"It necessarily follows . . . it was prejudicial error for the court to give the second instruction above set out, which it gave upon its own motion. For in this second instruction the court told the jury that they might disregard altogether the opinions of the experts testifying in the case if, from all the facts and circumstances in the case, they believed that such opinions were unreasonable. In other words, the court, in effect, instructed the jury that if there were facts and circumstances in the case, testified to by lay witnesses, which the jury believed and which rendered the opinions given in the case by expert witnesses unreasonable, then the jury were at liberty to reject altogether the opinions of the experts. As we have already noted, such is not the accepted rule, and to so instruct the jury was highly prejudicial to the rights of the appellants. . . . The judgment is therefore reversed."

CORRESPONDENCE

LIGHTS THAT ARE HIDDEN

An advertisement in a local *newspaper* stated that "few people who at some time or another have not suffered that terrific pain with 'neuralgia of the face' and yet not one in ten got instant relief with the remedies used or even understood the true cause of the ailment."

"Neuralgia is caused by pressure on the nerve fibers connected with the trifacial nerve of the face. This pressure is found in the neck. The small spinal segments in the neck are displaced enough to cause an impingement of those nerves, and neuralgia pain its the result. Relief is very certain under chiropractic adjustments; why suffer when there is no need of it? Let us explain how we can correct your ailment without the use of poisonous drugs."

E. L. Meyers, M. D., Chico, California, commenting on this says:

One who did not understand would say, "What is wrong with this advertisement?" First of all, it is a gross misstatement of facts, because the fifth cranial nerve or trifacial does not go near the neck; it is purely a cranial nerve having its origin within the skull, and its exit is through openings in the skull known as the "foramens, ovale rotundum and sphenoidal fissure and not between the vertebra of the *neck*," therefore, it could not be from vertebral misplacement causing an impingement upon the trifacial nerve.

We are, therefore, led to believe the person who wrote this advertisement belonged to the nine in place of the one who really understands the true situation. We who know and have made a lifetime study of conditions particularly due to disease, see the error not only in this advertisement, but in others of "wonder cures," patent medicines, so-called Chinese herb venders, and other cults that have taken root in America today.

Among the various "systems" of healing is the "osteopathic system," founded in Kirksville, Missouri, about thirty years ago. Their educational requirements at the beginning were very low, and are still deficient in quality or quantity of learning and upon the requirements for admission to other schools and colleges. Another "system" is chiropractic, with very low requirements for entry and only a short time for study—eighteen months. Whereas a regular medical student must study at the present time eight years, then after the eight years he is called in assembly and graduated; but he is still without the freedom of other "systems." He has a code of ethics, which is the bushel basket that forever hides his light. He must not advertise his individual ability to treat certain diseases, for if he does he is classed by his fellow-physicians as quack advertiser. Therefore, he has no way except his work to show his ability.

In my opinion, at the present time and age this is all wrong, as long as the class of advertising is true and not false. I think a medical man should be allowed this privilege without the odium of classification of *quack*. How is Brown to know the class and character of merchandise Smith has for sale without the medium of advertisement through the newspaper. Readers, stop and think of the conditions as they exist today! Who has founded and operates the hospitals of our land? Who, at great sacrifice to life and drudgery, has discovered the life-saving secrets, such as yellow fever, malaria, diphtheria, scarlet fever, diabetes, hydrophobia, tetanus or (lockjaw), smallpox, typhoid, and finally cancer in its early stages? The answer is the regular practitioner of medicine who has given his life to research work; and have they who have been the discoverers patented their ideas? *No*. It has been given to suffering humanity, without reward through the medium of the regular medical man.

Last, but not least, the physician gives his time and knowledge in establishing free clinics and health centers for the poor. Everything that has been discovered has been through exhaustive research of the regular medical man, and he is still working—working to add pleasant and comfortable years to human life by conquering the enemies of health.

"WHEN DOCTORS DISAGREE"

Under this caption (a quotation, by the way, from the San Francisco Daily News), are a few paragraphs in the May number of CALIFORNIA AND WESTERN MEDICINE. Why shouldn't doctors disagree? Disagreement has the authority of the greatest antiquity behind it. Adam and Eve disagreed with the Lord and were put out of the Garden of Eden. Some time later their sons disagreed and Cain killed Abel. As years went on the population became so disagreeable, individually and collectively, that the Lord sent the great flood to wipe off the earth. Centuries afterward, tribes and nations disagreed with each other and began warfare. To settle disagreements between individuals our courts were founded. Man disagreed with the circumstances surrounding animal life and began to wear cloths, live in houses, and cook his food. If his food disagreed with him, or the weather, or he got a disagreeable hurt, he felt the need of human aid. Hence, the founding of the profession of medicine and surgery.

In the Dorothy Ellingson case it is reported that Dorothy disagreed with her mother and then shot the mother. At the trial one set of attorneys bitterly disagreed with another lot of attorneys. Dorothy seemed to disagree with everybody in the courtroom, and the judge seemed perturbed also. Why did the News editor not notice some of these other disagreements, but single out the doctors for comment? Our civilization is founded on disagreements. Disagreement is the biggest and most popular thing in the world today. Any Democrat or Republican will swear to the truth of this statement.

ETHAN H. SMITH.

528 Flood Building, May 12, 1925.

To the Editor—In Dr. Miller's article on "Ringworm of the Scalp," in the March number of CALIFORNIA AND WESTERN MEDICINE, I found no mention made of quartz light therapy. This was a surprise to me, as I have had very good results with it in treating fungus infections.

A young man who had a very bad case of tinea barbae, covering nearly two-thirds of the beard region, of two months' duration was completely cured by two treatments carried to the point of vesication.

A young man of 16, with a skin lesion on the thigh and inguinal adenitis of four months' duration, declared by the pathologist to be a yeast infection, was immediately benefited and permanently cured by three weeks' treatment with quartz light.

The almost immediate improvement and ultimate entire cure in these cases, as well as others of minor degree of infection has converted me completely to the use of quartz light in all fungus infections.

I would like to know the experience of others in the treatment of such cases, for if quartz light will cure ringworm even of hairy regions, why risk x-ray?

F. F. ABBOTT, M. D.

Ontario, California.

Doctor Miller's reply:

"I think the following will answer the enclosed communication:

"The title of my article was 'Ringworm of the Scalp.' The discussion was, therefore, limited to fungus infections of the scalp. In the treatment of the disease in this location, quartz light therapy has not been found to be of value.

In the treatment of kerion fungus infections of the bearded region and in blastomycosis or coccidioides of the skin, quartz light therapy is undoubtedly of some value. However, I have never seen or read of any such rapid cures in these stubborn infections as Dr. Abbott reports. I am sure that a more detailed clinical and bacteriological report along with the technique of treatment of his patients would be welcomed by all of us.

Sincerely yours,

HIRAM E. MILLER."

MEDICAL STRAWS

By THE EDITOR

Experience is fallacious and judgment difficult

What Does This Signify?—"The school health agencies now control the means of communicable disease prevention and control," says an official publication of the Department of Education. "In other words," continues the author, "the school health service, including its staff of physicians, dentists and nurses, is best prepared to handle most of the positive health and physical efficiency program of the school."

LACK of law enforcement is a far worse thing than lack of laws. Our metropolitan towns of today and our Western wildernesses of yesterday combine their annals in recording conclusively this truth. Metropolitan crime statistics and the history of vigilance committees prove it. In the cities feeble enforcement encourages, protects, and multiplies our modern criminal population.—John Hays Hammond.

AS LONG as children—and dogs—take naturally and at once to me, I am quite willing to be called a bad mixer.—Percy Fridenberg, M. D.

Gratitude in Action—We give freely of our time to the clinics under the mantle of charity, and the prow of the Ship of State bunts us in the seat of the pants for being in the way.—Medical Pocket Quarterly.

In Which Class Are You?—If you are a partisan, you have one chance in two of being right. If you are a neutral, you have no chance of being right.—Clarence Darrow.

Worth Pondering—Some of our alleged health experts have adopted the ambitious policy of immortality for us all. But the facts remain that the centenarian lives half his life *after the full enjoyment of it has died*, and that the much greater proportion of old people is hardly likely to make for social vigor. The extension of the average length of life is filling the streets with the aged, and the falling death rate, bringing in its train a falling birth rate, is making our children grow scarcer.—E. M. Nicholson.

If This Is True, Why Educated Doctors?—"The ferreting out of beginning physical defects and beginning communicable conditions," says the California State Board of Health Weekly Bulletin, "can be done very effectively by the teacher."

The ferreting out of beginning physical defects is the most difficult of all phases of the practice of medicine.

"The treatment of drug addiction is a doctor's job."—Louise B. Deal, M. D.

More Important Than Living Long—Half the misery of human life might be extinguished by mutual offices of compassion, benevolence, and humanity.—Joseph Addison.

WE ARE prone to discuss medical matters from the standpoint of their elaborate and conspicuous episodes among the well-to-do or the brilliant and well-co-ordinated activities of hospital life. It must be borne

in mind that the mass of medical experience lies among the working people.—Henry B. Faville.

SHAW lies brilliantly, impartially, and epigrammatically, about soldiers (Arms and the Man), physicians (Doctor's Dilemma), physical love (Devil's Disciple) and preventive medicine (Prefaces), and however successful this brilliancy may be with the general public, he discredits himself, as far as essential honesty is concerned, with those who are in the habit of facing things as they are.—Medical Review of Reviews.

He was Ill When He Said It—"Occasionally only do we meet with an example of vigorous health continued to old age; hourly do we meet with examples of acute disorder, chronic ailment, general debility, premature decrepitude. Not to dwell on the natural pain, the weariness, the gloom, the waste of time and money thus entailed; only consider how greatly ill health hinders the discharge of all duties, makes business often impossible, and always more difficult; produces an irritability fatal to the right management of children, puts the functions of citizenship out of the question; and makes amusement a bore."—Herbert Spencer.

University Publicity—Are our universities destined to replace barbershops as centers for the dissemination of jokes? It begins to look like it, doesn't it?

Opportunity

They do me wrong who say I come no more
When once I knock and fail to find you in,
For every day I stand outside your door
And bid you wake and rise to fight and win.

THE index of community intelligence is represented in the percentage of voluntary vaccination. Only children and fools *must* be protected against smallpox.—Ohio Health News.

"Pity 'Tis True"—An unscrupulous physician talking to a sensation-seeking reporter can do more harm to scientific medicine in one interview than can be undone by the united effort of a hundred conscientious and capable physicians talking to the public.—Indiana Medical Journal.

THE only advertising that will redound to the professional credit of the physician is that which he does not do, but which he gets, and which he cannot keep from getting as the result of efficiency in the practice of his profession in a professional manner."

NO CIVILIZATION can long endure a universal disdain for work, for labor.—Dean J. B. Johnston, University of Minnesota.

THE young doctor having been thoroughly grounded in life as it is not, and taught to think in terms of a language that adapts itself easily to ambiguity, can it be wondered that he does not understand what a practical world wants to buy from him and really what he has to sell. Let us not fool ourselves, as doctors we sell knowledge and service.—New Orleans Medical and Surgical Journal.

SYPHILIS," states a writer (New York State Journal of Medicine), "is the second principal cause of the cardio-vascular diseases which are now by far the leading causes of death in the United States. Lamb estimated cardiac involvements to be present in 50 to 75 per cent of all syphilitics."

And still the crusaders are out to prevent heart disease by diet!

Hospital sterilizing safety in your own surgery

The risk in using partly sterilized goods is as great in a small hospital or clinic as in a large institution. In either place the danger from infection is too large to be neglected.

It more than pays to have a wide margin of safety on your side, no matter where you operate.

The CASTLE 1336 combination gives you that protection. It has a 10x20" autoclave, eight gallon tanks for hot and cold water with a filter, and a 19" instrument sterilizer. It is ideal for community hospitals, clinics, and small surgeries.

WELLSWORTH MONAXIAL BIFOCALS

The Supreme Achievement In Bifocal Grinding

- 1—Monaxial lenses are made of one piece of glass.
- 2—Monaxial lenses eliminate the "Jump" from distance to reading fields.
- 3—Monaxial lenses eliminate the blind area.
- 4—The distant and near fields merge. Positively no prismatic displacement.
- 5—They overcome muscular imbalance due to bifocal addition.
- 6—Can be used in any degree of myopia, as in hyperopia.
- 7—Thoroughly practical where two eyes are widely different.
- 8—Eliminates the danger of false steps, often caused by the prismatic displacement of ordinary bifocals.
- 9—Wellsworth Monaxial lenses give myopes the same bifocal comfort as hyperopes—and hyperopes receive greater comfort than ever.

Wellsworth Monaxial bifocals are the most comfortable and practical of all bifocals—the highest degree of optical and mechanical development yet devised. Nothing has been permitted to interfere with the best optical performance, therefore the reading portion is slightly more visible than in other bifocals of the better grade, where everything has been sacrificed for appearance. The patents under which Wellsworth Monaxial lenses are made, are owned and controlled by the American Optical Company.

Specify Wellsworth Monaxial on your next bifocal prescription.

Renal Failure Casts—During the course of a quantitative study of the formed elements of the urine, Thomas Addis, San Francisco (Journal A. M. A.), noted the occasional occurrence of a certain type of cast whose most distinctive characteristic is a quite unusual breadth. There are three distinct varieties of these broad casts, but they seem to be only different forms of the degeneration of a single type, since every stage of gradation from one variety to the other is often found in the same urine. The first variety, and the one from which the other two apparently develop, is a cellular cast in which even the nuclei of the cells can sometimes be distinguished. These cells are mononuclear, though occasionally two round or oval nuclei are seen in the same cell. They are somewhat larger than polymorphonuclear white blood cells, and no granules have been demonstrated. But much more commonly only rather faint cellular outlines can be traced on the surface of the cast, and at this stage it begins to have a glassy, refractile appearance. As the cell outlines grow still more indistinct and the case becomes almost homogeneous, the second variety is approached, the broad waxy cast, which in every respect except its breadth is indistinguishable from the ordinary waxy cast. This is the variety that is least frequently seen, however, for most of the broad cellular casts degenerate into the third variety, the broad granular cast, the variety that is nearly always present in the greatest abundance and sometimes is the only form that can be found. Under the low power of the microscope they look black, as if they were composed of graphite particles. Under the high power, coarse granules can be seen, which are closely packed toward the center, but are sometimes frayed out toward the periphery, making the outline irregular and giving the impression that the cast is in process of disintegration. The conception that the broad granular and waxy varieties are derivatives of the broad cellular cast, which is suggested by their morphology, is further supported by the fact that in concentrations of methylene blue that leave hyaline casts unaffected, the granular, as well as the cellular casts, stain deeply, and that a varying amount

SAFE MILK FOR INFANT FEEDING

The Original

During the hot summer season care should be exercised in the selection of milk used for infant feeding.

Horlick's Malted Milk is prepared from clean, fresh, full-cream milk, combined with the extracts of malted barley and wheat. Well balanced, partially pre-digested and conveniently prepared.

"Horlick's" is readily adapted to individual infant feeding, strengthens and invigorates delicate children, and is used with benefit as a nourishing food-drink for nursing mothers. Prescribed by the medical profession over one-third of a century.

*Samples and literature prepaid
upon request*

RENAL FAILURE CASTS

(Continued from Page 766)

of the dye is also taken up by the broad, waxy cast. Broad casts remain unaltered even in distilled water. For this reason they may be found in dilute urine in which hyaline casts are never seen. Again, in any given concentration of sodium chlorid, hyaline casts remain undissolved only within a relatively narrow range of pH variation, but broad casts are not appreciably affected even by hundredth normal acid or alkali. Yet they sometimes disappear from urine within a very short time and under the microscope they have been seen to grow more and more faint and indistinct, and ultimately to disappear altogether; although, when they have been freed from urine by repeated centrifugalizing from changes of salt solution, they may remain unaltered for weeks. Addis terms these casts renal failure casts. In every case in which broad casts composed all or almost all the casts found in the urine, the concentration of urea in the blood was over 100 mg. per hundred cubic centimeters. In every case in which the outcome is known—with one exception, an instance of mercury nephrosis—the patient died in true uremia. In every case of true uremia this sediment was found, with the exception of patients with pyonephrosis and macroscopic pyuria. The clinical value of a knowledge of this association is obvious. Some of these patients came with superficially trivial complaints, such as headache or nausea, and it was this quite pathognomonic urinary finding that first indicated the real gravity of their condition. When only some of the casts were broad, there was always some degree of renal failure. But in certain patients during the height of activity of bacterial infections, a considerable proportion of the casts were broad, although there was no marked impairment of renal function; while in other patients whose general condition was good, none of the casts were broad, although there was a pronounced reduction in the functional capacity of the kidney.

If its for the physician, hospital or sickroom, we have it

Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in—

ALQUA WATER contains the alkaline salts found normally in the human body. Physicians will find it invaluable where alkaline treatment is indicated. Not only is it very effective in the treatment of most acute and chronic diseases caused or accompanied by acidosis, but it is an ideal preventive, in that it neutralizes destructive acid by-products in the system.

GLACIER SPRING WATER with which Alqua is prepared, originates in the upper glaciers of Mt. Shasta, California, U. S. A., (Elevation 14,442 ft.) Its great purity without artificial treatment, renders it especially suitable for affinitization with the added salts, thus forming a combination that is remarkable as an alkaline water. Glacier water is released from the earth at Shasta Springs where it is put into block-tin lined carriers and transported to the Company's laboratory where the alkaline salts are scientifically added under the directions of an expert chemist, thereby creating, through the united efforts of science and nature, the wonderful medicinal virtues of Alqua Water. ASK YOUR PHYSICIAN ABOUT IT.

At All Druggists

The Management of an Infant's Diet

Mellin's Food—A Milk Modifier

It has long been recognized that the stated purpose of Mellin's Food is supported by a foundation in keeping with the essential problem of the artificial feeding of infants.

Through the acceptance of the principles of Mellin's Food and the ever-extending use of Mellin's Food as a milk modifier, a method of procedure has gradually developed to finally evolve into

An Established System of Infant Feeding.

The simplicity of this system, and the eminently satisfactory results from its application in the feeding of both well and sick babies, are matters worthy of serious consideration.

This system is set forth clearly and concisely in "Formulas for Infant Feeding". A copy of this book, bound in leather, will be sent to physicians upon request.

Mellin's Food Co., 177 State Street Boston, Mass.

SITUATIONS WANTED—Salaried Appointments for Class A physicians in all branches of the Medical Profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan, Chicago. Established 1896. Member The Chicago Association of Commerce.

SITUATION WANTED—INTERNIST, 38, MARRIED, PROTESTANT, Desires association with strictly ethical group. 1907 Michigan graduate; 2-year interne service in industrial hospital; 10 years general practice and four years in internal medicine and X-Ray in West. For past 1½ years engaged in post-graduate study in foremost teaching medical clinic in the East. Have had unusual training in clinical medicine, clinical pathology and fundamental diagnostic procedures including blood chemistry and electrocardiography. Only high grade offers will be considered. Address Dr. 530, CALIFORNIA AND WESTERN MEDICINE.

LOCUM TENENS— POSITION FOR MONTH OF JULY WANTED IN Bay region, by member California Medical Association. Address Dr. 650, CALIFORNIA AND WESTERN MEDICINE.

WANTED—LOCUM TENENS OR ANY WORK. PREFERABLY NEAR Coast. Age 32; single. Have been practicing in California two years. Special training in E. N. and T. and experienced in Industrial work. Address Dr. 625, CALIFORNIA AND WESTERN MEDICINE.

FOR SALE—A WELL EQUIPPED LABORATORY, CLINICAL AND X-Ray; of good age and excellent reputation is ready for prompt sale. Enviale location. References required in order to continue "good will" of laboratories. Address Box 675, CALIFORNIA AND WESTERN MEDICINE.

WANTED—MALE LABORATORY TECHNICIAN, WITH WORKING knowledge of Serology and Blood Chemistry. Part or full time. Reply by mail stating references and remuneration required. Box 600, CALIFORNIA AND WESTERN MEDICINE.

Hepatic Cirrhosis in the Philippines—A. G. Sison, A. B. M. Sison, and W. De Leon (Journal of the Philippine Islands Medical Association) have supplied us with an unusual amount of most exact information about cirrhosis of the liver. The facts accumulated by the authors have been taken from the combined clinical and pathological records of the Medical College and its hospitals. While the data and discussion are intended to apply to the Philippines, similarly careful work may show that the facts are more widely applicable than we have been taught to realize.

Effect of Epinephrin by Oral Administration—This study by William C. Menninger, Topeka, Kan. (Journal A. M. A.), is based on a series of observations in the administration of epinephrin by mouth in various types of hyperthyroid cases. To date, a series of fourteen observations has been made on nine patients. Of this group, three have given a very definite and in one case a marked reaction, and two others have given slight reactions. Of the three cases in which the reaction was marked, the blood pressure rose (systolic) 30 mm. in one case, 50 mm. in the second, and 110 mm. in the third. The pulse remained practically constant in the first two, but increased fifty-two beats a minute in the third. In all three cases, epigastric and substernal pain and nausea occurred. Vomiting, sweating and increased tremor occurred in two cases. In the two cases giving slight reactions, the blood pressure (systolic) rose in one case 12 mm. with a pulse increase of 20, and 18 mm. in the second with a pulse increase of 10. In both cases there was epigastric "burning" and distress. These reactions were slight and might be disregarded, excepting that control observations with smaller doses on the same patients produced no objective or subjective effects. At present, conservatively, the only conclusion to be made is that epinephrin may produce marked systemic effect on the circulation in some cases of hyperthyroidism when administered by mouth, the effect resulting from absorption through the gastro-intestinal canal and not from the mouth or throat.

ACIDOSIS

By some investigators ACIDOSIS has been designated as a diminution of the alkalinity in the blood; by some as an excess of acid in the blood; by others as a lessening of reserve supply of fixed bases in the blood.

If the acid combining power of the blood is impaired BY A LACK of the alkalies, sodium bicarbonate and sodium phosphate, and may be built up by the process of food ingestion, *may we ask* attention to CALSO WATER, which is rich in the potential alkalies.

Pellagra Secondary to Lesions of Stomach Interfering With Nutrition—An interesting side-light is thrown on the subject of pellagra by the occasional appearance of the disease in patients with faulty food utilization due to some gastro-intestinal lesion. Three such cases are reported by William L. Bender, San Francisco (Journal A. M. A.) Pellagra developed in one of these patients during a period of jejunal feeding necessitated by deformity of the stomach by a benign ulcer, and in the other two cases during progressive carcinomatous pyloric obstruction. Only two similar reports have been found in the literature. In each of these three cases, pellagra developed after the stomach lesion had seriously interfered with the passage of food for some time. In one case the disease developed during the course of duodenal feedings with good animal protein content, improved when this was increased, and disappeared on a general diet by mouth. Surgically relieving gastric retention, in the second case, and permitting a full diet resulted in improvement of the pellagrous condition, though the patient was dying of cancer. The trial of improving the diet was impossible with the third patient, who died two weeks after operation. In these three cases of this report, the only apparent cause for pellagra was the interference in nutrition, another piece of evidence in favor of the dietetic origin of the disease.

“Case”—“Case” is the incidence of a disease, the totality of the symptoms and of the pathologic and other conditions; “patient” is the human being, the man himself. “The case had quite a temperature,” “I put the case to bed,” “This case was taken ill three weeks ago,” “I sent the case out for a walk”—these and similar expressions are found continually in manuscripts; the error nearly always is in using “case” for “patient,” seldom the reverse.—From “The Art and Practice of Medical Writing by Dr. G. H. Simons and Dr. M. Fishbein (Journal A. M. A.), which every medical author should study and apply in the preparation of his manuscripts.

ALUM ROCK SANATORIUM

FOR THE TREATMENT OF TUBERCULOSIS IN ALL ITS FORMS

The Sanatorium adjoins Alum Rock in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

CALCREOSE

R. RAMSDEN WADE reports (Brit. M. J. 1: 158, Jan. 24, 1925) having had good results from the administration of creosote in the treatment of cases of influenzal pneumonia and chronic influenza which are very liable to be mistaken for phthisis.

POWDER—TABLETS
SOLUTION

CALCREOSE (calcium creosotate) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime. It has the pharmacologic activity of creosote, but apparently does not have any untoward effect on the stomach.

BOOK REVIEWS

This column is conducted solely in the interests of California and Western Medicine readers. Critical comment, favorable and unfavorable, purely from the standpoint of the interests of the medical reader, will be made about books selected from the larger number acknowledged in the Books Received column. The advertising columns are open to book publishers who wish to make additional statements about their publications.

A Manual of Obstetrics. By John C. Hirst. 2nd ed. Illustrated. 551 pages. Philadelphia and London: W. B. Saunders Co. 1924.

The second edition of "A Manual of Obstetrics," by John C. Hirst, covers the field of obstetrics in sufficient detail to be of much value to the busy practitioner of medicine. It is not too detailed to prevent its being very practical.

The chapters on dystocia and mechanism of labor are well written and constitute a splendid study for anyone called upon to do obstetrics. C. D. H.

Developmental Anatomy. A Textbook and Laboratory Manual of Embryology. By Leslie Brainard Arey. 433 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1924.

Arey's Developmental Anatomy, following the former textbook of embryology by Prentiss and Arey, which was published by Saunders a good many years ago, seems a great improvement over the previous work. It is a work of merit for anyone interested in man and his anatomic development. The volume is remarkably complete, is well illustrated, and is clear and concise.

The structural rather than the functional aspect of the developmental history of the structure of the body are emphasized. From the practicing surgeon's point of view, the section of the book on organogenesis is well worth its price. C. L. C.

The Relative Position of Rest of the Eyes and the Prolonged Occlusion Test. By F. W. Marlow. 96 pages. Philadelphia: F. A. Davis Company, 1924. Price \$2.50.

The author deserves credit for stressing a relatively little known and hitherto neglected test which is of distinct value in certain cases. Its study and application can be recommended to those ophthalmologists who have

The washroom of the U. S. Marine Hospital's laundry, showing "American" Cascade Washers and other "American" units.

Uncle Sam Comes Back for More...

It's a compliment to have "American" laundry machinery chosen by the United States Public Health Service.

It's an even greater compliment when one installation of "American" machinery in a government hospital leads to another.

That is what has happened in the U. S. Marine Hospitals, conducted for research purposes by the U. S. P. H. S.

"American" machinery was first installed in the United States Marine Hospital at San Francisco. The satisfaction that it is giving is shown by the fact that now the United States Marine Hospital

in Chicago also has an "American" equipped laundry.

And it is, of course, as advantageous for a private institution as for a government hospital to operate its own laundry with "American" machinery. Closer supervision of the work, with the certainty that it will always be up to the hospital's standards, as well as more efficient operation, are some of the benefits.

Valuable data on hospital and institutional laundries, collected over a period of years, are at your disposal. You are also welcome, at any time, to consult our staff of engineers—laundry experts who will gladly answer any question of laundry management which may be of interest to you.

BOOK REVIEWS

(Continued from Page 780)

not employed it. It is regrettable, however, that the chapter on treatment is so short and is restricted to some general statements of satisfactory results. O. B.

Basal Metabolism in Health and Disease. By Eugene F. DuBois. 372 pages. Philadelphia and New York: Lea & Febiger, 1924. Price \$4.75.

It is a pleasure to review a book such as Doctor DuBois has written. It is complete, concise and readable. Being one of the pioneer workers in basal metabolism in this country, the author is a recognized authority on his subject. The work is even more comprehensive than its title implies. Over fifty pages are devoted to discussion of diseases of the thyroid touching on other aspects than those concerned with basal metabolism changes.

About one-third of the book is devoted to physiological metabolism, technical methods, etc., and the remaining two-thirds to changes in metabolism accompanying pathological states.

An author and subject index complete the book, which is recommended to the practitioner as a guide to indications for and meaning of basal metabolism estimations.

J. M. R.

Principles of Surgery for Nurses. By M. S. Woolf. 350 pages, illustrated. Philadelphia and London: W. B. Saunders Company, 1925.

The author in his preface promises a simple statement and explanation of surgical affections for the use of nurses, and in the twenty-four chapters of his book has in practically every instance carried this out admirably.

In the introduction a brief survey is given of many important historical data. The first three chapters are devoted to a consideration of micro-organisms and their effect in the body. This discussion is, in the main, very satisfactory. Why the section on burns and scalds and skin grafting is included here rather than in the section dealing with loss of tissue is less clear.

The chapters dealing with surgical diseases of the skeleton and accompanying soft parts are clear, but are possibly open to the criticism of being too comprehensive for the majority of those for whom written. This brings up the question of how much we should require of the trained nurse, and my criticism may here be without foundation.

Injuries and diseases of the blood vessels are well and briefly covered and the chapter on hernia is good; that on diseases of the alimentary tract seems, at least in places, beyond the scope suggested by the book's title.

Surgical conditions of the special sense organs, central

nervous system, and genito-urinary systems are well and, in the main, briefly handled. If more is given than the title would seem to demand, this is explained in advance in the preface.

The book is well written, written in a pleasing and easy style that should recommend it strongly to those for whom it was prepared. It shows careful preparation on the part of the author. His illustrations are usually such as to round out the text and are for the most part happily selected. It is a book that should serve well the nurse studying it and contains many suggestions in the well-executed summaries for such students who desire to pursue the subjects further.

P. K. G.

"Under the 'Panel System' existing in England," says the Ohio State Medical Journal editorially, "millions of British citizens pay a small yearly stipend, in return for which they secure medical care and treatment for the twelve months. Panel physicians have many hundreds of patients. Their salary is fixed. They have no further interest in patients than to 'get them out of their offices as quickly as possible.' The incentive to keep abreast of the times in scientific medicine has gone, for superficial service serves as well as thorough service. They cannot lose their patients; they cannot miss their income. As the final analysis, the English people have traded a small money consideration for a 'pottage of supersocial medical service.' The 'panel physicians' have attached themselves to a payroll and a large array of 'assigned patients. The physician who is conscientious, who wishes to give his patients the very best, cannot compete with the 'panel system,' which embraces most of the English population. He cannot become a 'panel physician' because he is unable to give the necessary time to each case. This may be why thousands of physicians are out of work in London."

"Honesty is not only a part of the art of medicine," says Frank A. Ely (Iowa Medical Journal), "but it is the chief factor in the art of living. . . . It takes a long time to establish a reputation for honesty, but when such a reputation has been established it becomes one of the basic constituents of the art of medicine, and is the steel cable that moors the physician's clientele to him."

HOSPITAL FOR CHILDREN AND TRAINING SCHOOL FOR NURSES

A general hospital of 275 beds for women and children. Thirty beds for maternity patients in a separate building, newly equipped.

Complete services of all kinds for women and children. Infant feeding a specialty.

House staff consists of three resident physicians and eight internes.

Accredited by the Council on Medical Education and Hospitals of the American Medical Association.

Institutional member of League for the Conservation of Public Health.

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of

them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) \$45.00 per week and upward.

RADIODOR

The only Electric Vaporizer that is safe and efficient in the Hospital and Home treatment of respiratory affections. Quick, clean, easy and economical to operate. The demonstrations at the

American Medical Association Convention and at the Annual Conference of the Hospitals of California have convinced thousands of physicians and hospital superintendents throughout the nation of its superiority.

THE RADIODOR COMPANY

240 Stockton Street San Francisco, California

Kindness—Ah! here is the keynote of medical art. Kindness is the one trait which, when possessed by the physician, can make up for a multitude of artful deficiencies. *Clumsy hands in kindly service become gentle.* A kindly smile beaming through an unkempt beard is like sunrise in the cane-brake. A kindly sentiment crudely expressed is like a drink of crystal spring water from an iron dipper. Kindly silence is frequently resonant in its expression of sympathy. Kindness cannot be assumed or imitated. It emanates alone from love.—Frank A. Ely, M. D. (Iowa Medical Journal).

Physicians Must Meet the Demands of Increasing Public Intelligence—"It is an age where the public demand efficiency, whether it be regarding the performance of a motor car or the family physician," says Edward Beardsley (New Jersey Medical Journal). "The public is intelligently interested in medical problems. If I interpret the mental attitude of the intelligent public correctly, I believe that they are demanding efficiency in medical diagnosis and treatment more than ever before."

X-Ray Laboratory of Dr. A. D. Willmoth, Louisville, Ky. Victor Equipment Throughout

Time and Use Reveal Victor Quality

As months and years pass, the Victor X-Ray machine installed in the physician's office or in the specialized roentgenological laboratory unfailingly responds to the demands made upon it. Day after day, the same trustworthiness in operation, the same certain results as in the beginning.

Thus time and use reveal the quality painstakingly built into every Victor X-Ray machine.

There are simple Victor X-Ray machines which meet the demands of general practice, and powerful diagnostic and deep-therapy apparatus for institutions and laboratories. The same Victor quality is built into all.

We shall be glad to suggest the type of Victor installation best calculated to meet the requirements of the physician in general practice, the hospital or specialized laboratory.

March 9, 1925.

Mr. L. B. Miller,
Victor X-Ray Corp.,
254 Sutter St.,
San Francisco, Calif.

Dear Mr. Miller:

Enclosed you will find a cashier's check for \$874.28,
covering the items on the attached list.

I wish to take this occasion to express my appreciation
of the uniform courtesy and excellent service which I have
received from every member of the Victor X-Ray Corporation
with whom I have had dealings. My first experience with the
Victor organization and its apparatus was in the x-ray lab-
oratory of the University of Pennsylvania, where I studied
under Dr. Henry Pancoast, Professor of Roentgenology. From
that time on, the service rendered me by your representatives
has been all that anyone could desire, and I have never pur-
chased an article from your company which was in any way
misrepresented. I feel, therefore, that any physician who
is acquainted with the character of the service rendered by
Victor in this vicinity would be exceedingly unwise to trust
his business in any other hands.

Your local representative has done everything in his
power to assist me with my apparatus and to maintain the
high standards of the company he represents.

Very truly yours,

Edwin L. Mott.

Analysis of
KLIM
 POWDERED WHOLE MILK

	<i>Dry</i>	<i>Liquid *</i>
BUTTERFAT	28.00%	3.33%
CASEIN	21.28%	2.53%
ALBUMIN	5.46%	.65%
LACTOSE	38.00%	4.53%
ASH	5.76%	.69%
WATER	1.50%	88.27%
CALORIES (per ounce)	149.	18.

* 4½ Ounces to a quart of water

KLIM is completely soluble in water of any temperature

When Used in Infant Feeding

Reliquified KLIM at normal strength has the same analysis and caloric value as natural whole cow's milk and is subject to the same modifications when used in infant feeding

Recognizing the importance of scientific control, all contact with the laity is predicated on the policy that KLIM be used in infant feeding only according to a physician's formula.

KLIM has a high nutritive and assimilative index

THE casein of KLIM, when attacked by digestive juices, coagulates in a flocculent mass rather than in the tough curds characteristic of natural milk.

The butterfat of KLIM retains the globular form of natural milk, but in a much finer division.

The result must be a speedier and more complete metabolism, less inclination to colic, and an absence of the regurgitation which frequently accompanies the feeding of natural milk.

Well Deserved Success

LESS than three years ago S. M. A. was comparatively unknown to physicians throughout the country, yet by sheer merit alone it has steadily advanced to a prominent position among all fine products for the infant's diet.

We believe no other product has ever achieved such success in such a short time or made so many friends among physicians.

Once you have tried S. M. A. you will agree that its success has been well deserved, and we want you to have that experience. Just write us for trial package and literature.

FIVE DOLLARS A YEAR, SINGLE COPIES FIFTY CENTS

(Continuing the California State Journal of Medicine)

When the Infant Has Diarrhoea

PROTEIN MILK feeding to the infant with summer (fermentative) diarrhoea is generally followed with gratifying results.

PROTEIN MILK made with MEAD'S CASEC is simple to prepare.

CASEC is one of the physicians' first thoughts for infants of this type.

Samples of CASEC together with literature describing its use in diarrhoeas furnished immediately on request.

The Mead Policy

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

Authors are responsible for all statements, conclusions and methods of presenting their subjects. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the method of presenting their subjects. It is believed that the author's presentation determines to no small degree the value of his conclusions.

Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented as little disturbed as possible by the editors.

However, the right to reduce or reject any article is always reserved.

THE PREVENTION OF HYDROPHOBIA (RABIES)

OF LATE a great many cases of rabies in dogs have been reported from various parts of the United States. These reports show that the infection is widely distributed. No section of the country is entirely free from rabies. The dog, from the very nature of his habits, is the main disseminator of this disease.

The physician is called on today as never before to guard his patients against rabies. Only one form of treatment is available—preventive vaccination before the appearance of symptoms.

Whitmore (Tice, Practice of Medicine) lists the conditions calling for antirabic vaccination after a dog bite, as follows:

1. If rabies is in the district, antirabic vaccination should be started at once and continued until the dog can be observed for ten days.
2. If the dog dies or is killed or disappears in less than ten days after biting the patient.
3. If the dog is unknown.
4. If the dog is living and after observation for ten days develops rabies, dies under suspicious circumstances, or is sick.

Rabies Vaccine (Cumming), prepared in the Biological Laboratories of Parke, Davis & Co., is a sterile suspension of brain tissue from rabbits killed with fixed virus (death with paralysis in seven days). The infectivity is removed by dialysis, while the full immunizing properties are retained. No report of injurious results to the patient following treatment has ever been received.

Few specific prophylactic agents present a record for dependability comparable to that attained by Rabies Vaccine (Cumming). During the many years that Rabies Vaccine (Cumming) has been supplied to the medical profession, not one complaint of distinct failure relating to this product has ever reached the Laboratories. Considering the many thousands of patients treated with Rabies Vaccine (Cumming), this is a truly remarkable record.

The Vaccine is obtainable on short notice by all druggists, being carried in stock under proper conditions for its preservation, by the home laboratory and our branches.

A Definite Habit

PETROLAGAR is issued as follows: PETROLAGAR (Plain); PETROLAGAR (with Phenolphthalein); PETROLAGAR (Alkaline); and PETROLAGAR (Unsweetened, no sugar).

PETROLAGAR has been accepted for New and Non-official Remedies by the Council on Pharmacy and Chemistry of the American Medical Association.

Failure of the individual to adhere to a definite time at which the bowels are to move is the most common factor in causing constipation. Much constipation is caused by waiting for an inclination and neglecting a definite time for bowel movement.

The establishing, therefore, of a regular, definite "Habit Time" is the most important factor in the treatment of constipation.

The administration of cathartics tends to aggravate instead of relieve the condition. Correct diet and exercise are valuable in restoring the normal function of "Habit Time."

A mechanical aid is also valuable, and PETROLAGAR was originated to provide this mechanical aid.

It is an emulsification of 65 per cent pure mineral oil with agar-agar, which affords thorough lubrication, a soft, easily moved fecal mass, and it is of great assistance in teaching the bowel to move normally, without having to resort to the obnoxious cathartics.

TRUTH ABOUT MEDICINES

New and Non-official Remedies

(Abstracts from reports of Council on Pharmacy and Chemistry, A. M. A.)

Note—These do not represent all of the actions of the Council, but they do represent those remedies manufactured by firms who co-operate with California and Western Medicine in its advertising columns, and thereby with the physicians in California.

In addition to the articles enumerated in our last report, the following have been accepted:

Parke, Davis & Co.—Typhoid Vaccine (Prophylactic), 30 cc.; Typhoid Paratyphoid Vaccine (Prophylactic), 30 cc.

Powers-Weightman-Rosengarten Co.—Stovarsol; Stovarsol Tablets, 0.25 gm.

Rabies Vaccine (Semple)—Anantirabic Vaccine (New and Non-official Remedies, 1925, p. 342), prepared according to the general method of David Semple (phenol killed). It is marketed in packages of seven syringes, each containing 2.5 cc. Cutter Laboratory, Berkeley, Calif. (Journal A. M. A., May 16, 1925, p. 1497).

Bromsulphalein (H. W. & D.)—Disodium Phenol-tetrabromphthaleinsulphonate—The disodium salt formed by the interaction of tetrabromphthalic acid (or anhydride) and phenol with subsequent sulphonation. It contains from 37 to 38 per cent of bromine. Bromsulphalein (H. W. & D.) is used as a test of liver function; the amount remaining in the blood stream after intravenous injections, as determined colorimetrically, is considered a measure of hepatic dysfunction. Bromsulphalein (H. W. & D.) is supplied in ampules containing 3 cc. of a 5 per cent solution. Hynson, Westcott & Dunning, Baltimore (Journal A. M. A., May 23, 1925, p. 1573).

Scarlet Fever Streptococcus Antitoxin—Lilly (Unconcentrated)—It is prepared by the Dochez method. Each cc. neutralizes at least 10,000 skin test doses of scar-

(Continued on Page 814)

NOW—for Stubborn Summer Coughs!

YOU know how stubborn most summer colds are. And after the cold itself has been broken, how the racking cough hangs on and afflicts the patient for days to come before it disappears entirely.

Right here is a condition in which Thiocol Syrup 'Roche' will prove particularly useful to you. For Thiocol doesn't just temporarily subdue the symptoms, like most cough remedies, but exerts the full beneficial influence of Guaiacol, its active principle, upon the respiratory tract. This syrup isn't too sweet, like so many cough syrups, and does not upset the digestion; nor does it constipate. It is a simple remedy, containing only one drug—Thiocol—and is free from any narcotic or palliative constituents. It is never advertised direct to the laity and is intended for prescription only.

Why not try Thiocol Syrup 'Roche' in your next cases of summer coughs and colds? Please use the coupon and we shall gladly send a complimentary bottle for your observation or for use in your family.

The Hoffmann-La Roche Chemical Works, ^{New York}

4-T-1

The Selection of a Sanatorium

Attention of physicians is called to the urgent need and demand for an up-to-date institution for the scientific care and treatment of psychopathies, functional or organic nervous patients who are not subject to state hospital commitment, and for whom there are inadequate private places except those of a mere boarding-house character devoid of scientific directorship or resident physician and more concerned with financial returns than the recovery of patients.

Our state hospitals are intended to meet this demand, but owing to limited funds are unable to furnish that degree of privacy, home comforts, select environment, close personal touch and careful individualization demanded by patients who are accustomed to and can afford to pay for same—patients to whom money is no object provided they can be restored to health.

Unselfishly, in the interest of medical science to mutual advantage of physician and patient, the Grande Vista Sanatorium proposes an extensive program of reorganization and expansion, placing its directorship into the hands of a medical board who will be authorized to issue shares of stock in the institution to physicians who are in sympathy with this project, and who will lend their good-will and moral support towards its upbuilding.

All physicians of good repute are requested to join in the furtherance of this project, which will prove to their interest, as well as a blessing to their patients.

let fever toxin. Marketed in Packages of one vial containing 20 cc. Eli Lilly & Co., Indianapolis, Ind.

Scarlet Fever Streptococcus Antitoxin—Lilly (Refined and Concentrated)—It is prepared by the Dochez method. Each cc. neutralizes at least 20,000 skin test doses. Marketed in packages of one vial containing 10 cc. Eli Lilly & Co., Indianapolis, Ind.

Hyperpnea as Method of Diagnosis—L. E. Grimberg, New York (Journal A. M. A.), undertook to try his method on patients suffering from purely functional conditions. He selected five patients with an established diagnosis. The cases were classified as hysteria, anxiety, neurosis, and psychoneurosis. All the patients were women, their ages ranging between 18 and 30. The results obtained are briefly reviewed. Hyperpnea produces in the neurotic, in addition to involuntary movements of the fingers, tetany, and emotional outbursts. In hysterical patients, the outbursts are identical to the hysterical attacks of such patients. In organic cases it increases the symptoms, and may serve to establish (in some patients) the organic or functional character of the condition. The method is of use in patients suffering from hysteria with major attacks or from epilepsy who are unable to give a clear description of the attacks. In such patients, the method will reproduce the attack. Hyperpnea should be used cautiously in patients suffering from thyroid disturbances.

More people die from chronic diseases than acute. The proportion would undoubtedly be even much higher than the mortality statistics indicate, if every death certificate were carefully made out and showed the chronic disease which is largely responsible for the fatal result as well as the immediate cause of death or the terminal condition. Bulletin N. Y. Academy of Medicine.

HAY FEVER: ITS PHYSIOLOGICAL TREATMENT

POLLEN inhalation, and its subsequent effects, bring the prevalence of Hay Fever at this season. Cleansing of the nasal cavity—eliminating the pollens as they accumulate—offers the possibility of relief.

The Nichols Nasal Syphon accomplishes the washing out of the pollens, in a safe, simple and practical manner which will appeal to the thoughtful physician. It is indicated as

a valuable aid whatever other treatment is prescribed.

Patients may use the Nichols Nasal Syphon several times a day, in their own homes, for its cleanliness and simplicity will appeal to all. It is recommended that treatment begin early, before seasonal attack in order that annoyance may be totally avoided or minimized.

Some Also Avoid the Penalties of the Prohibition Law—"The common exemption of the practice of the 'religious tenets of a church' is, of course, defective," says H. E. Kelly, member of the Chicago Bar, "because the law can give no fair or defensible preference to the religion of a church member over the religion of a person who is not a church member. Such a provision must be held to exempt the religious tenets of any person to the same extent that it exempts the religious tenets of a church. Some persistent quacks have attempted to avoid this type of exemption by incorporating themselves into a church society in order to carry on their business of healing for pay under the privileges of churches unrestrained by the law, but they have met insuperable barriers in the courts, which have not been overawed by mere church machinery."

"The Golden Rule is an excellent religion for a physician to live and practice by," believes Edward J. G. Beardsley (Journal New Jersey Medical Society). "It is

not always those that are physically ill that most need our sympathy and help. Can a cultist do as much for the victim of psychasthenia as can a sympathetic, understanding, and interested physician? Have we not all neglected opportunities for being helpful to those suffering with both minor and chronic ailments? Such conditions may not be vitally interesting to the physician, but the patient cannot be in a position to understand or appreciate that point of view. The medical cults have always existed in some form or other and probably always will. *We must, as a profession, see to it that they do not exist as a protest against our failure to meet the needs, actual or psychological, of the public.*"

When proper attention is given to the treatment of chronic ailments, the charlatans' field for exploitation will rapidly shrink. At present it is this class of patients who are the prey of unscrupulous healers of many cults.—Bulletin N. Y. Academy of Medicine.

145 Guerrero Street, San Francisco

Accredited for Intern Training by the American Medical Association.
Accredited School of Nursing.
Open to All Members of the California Medical Association.
Institutional Member League for the Conservation of Public Health.

A limited general hospital of 150 beds, owned by the Archdiocese of San Francisco, and operated by the Sisters of Charity. All classes of patients are admitted except those suffering from communicable or mental diseases. The hospital was organized and incorporated in 1892. All buildings were destroyed by the fire in 1906. A complete new modern hospital was finished July 2, 1912. Mary's Help Hospital is well located, well constructed, well arranged, and well equipped for good service.

What is Nonspi?

NONSPI is an antiseptic liquid for Axillary Hyperidrosis which you can recommend to your patients with absolute confidence. It is a preparation which destroys armpit odor by removing the cause—excessive perspiration. This same perspiration, excreted elsewhere through the skin pores, gives no offense, because of better evaporation.

NONSPI has for years been used by innumerable women everywhere and is endorsed by high medical authority in America and Europe.

Physicians, surgeons and nurses find the regular use of NONSPI insures immaculate underarm hygiene and personal comfort, so essential to those who come in contact with the ill and sensitive.

To keep the armpits normally dry and absolutely odorless, NONSPI need be applied, in the average case, but twice a week.

50c a Bottle, at Toilet and Drug Counters.

Are You a Specialist?

Of course you are! You may be a "family doctor" of the good old variety—but nevertheless you are a specialist. You specialize in curing the physical [and sometimes mental] ills of humanity.

But the chances are you do not also specialize in business—investment securities—property values—collections and disbursements—the host of routine business details forced upon the attention of the professional man.

May we relieve you of the burden of those details? We are specialists. We can care for them at a lesser cost than you can yourself.

The Selection of a Physician

The selection of a physician for an operation or as a family doctor, is usually made with some care. We consult those who have employed physicians and are governed largely by their recommendations. But having selected a physician, we follow his advice. We trust him even to the extent of submitting to operations that may have serious results.

THE POINT IS, WE TRUST THE MAN
WHO KNOWS

Now, doctor, the institutions and the firms advertised in this Journal were carefully investigated before their announcements were printed here. The medicinal products were submitted to laboratory tests before they were accepted by the Council on Pharmacy and Chemistry.

On this same principle, that patients trust you about matters with which you are informed, so your publishers urge you to trust their judgment and *buy goods from the advertisers who are admitted to these pages.* Other considerations being equal, you should give your advertisers PREFERENCE because you know they are believed to be trustworthy. Don't speculate or experiment! Trust the APPROVED firms and goods.

The Hartung Hospital Silent Call Signal System

SAFE ————— SILENT ————— SIMPLE

Fully Guaranteed Troubleproof

Calling Station No. 115

The calling station herewith illustrated shows one of the sixteen combinations that we have to offer.

This station consists of the control switch with ball chain, slip connector, pull cord and pear shaped pendant attached. A slight pull on the cord illuminates a lamp in back of the ruby bull's eye located in the calling station visible to the patient, a lamp over the door in the corridor, a red pilot lamp in diet kitchen and utility room, and the lamp in the annunciator which shows the number of the room calling. These lamps continue to burn until the call is answered and the control switch knob is restored to off position.

The radio jacks furnish a connection for radio head sets for the reception of radio broadcasting, the radio receiving set being located in the office or wherever desired.

The duplex convenience outlet furnishes a connection for portable electric devices such as examination or reading lamp, electric fan, etc. Two appliances may be connected to this outlet at the same time.

Knowledge

*The attribute and useful tool
of the successful.*

Have you a knowledge of the savings and economy that can be effected by the use of your own laundry? If so, this message is not directed to you—it is for those who have not this knowledge. It is the desire of this corporation to assist those who do not operate their own laundry to a thorough knowledge of the benefits of this particular department.

Years of service in the planning of laundry departments for hospitals has given us a knowledge of the needs of such institutions that is yours for the asking.

We will not tell you that a laundry in your hospital will be an economy unless our survey proves that it will be. But we are interested in showing you the possibilities for saving if you can use such a department in your hospital.

Are you interested in gaining this knowledge? If so, write our nearest office.

A GOOD MOVE IN THE TREATMENT OF CONSTIPATION

ZED

Once the sufferer from chronic constipation is weaned away from the nightly pill habit, it is easier to make him see the importance of *natural* eliminative measures.

Show a patient that his daily diet can, and should, overcome intestinal stasis and he is quite willing to cooperate. Specify ZED as part of the dietetic regimen and you will find him doubly willing.

For ZED is something that most health-biscuits are not: *really tasteful!* A scientific blend of whole wheat, bran, milk, natural fruit and vegetable extracts—ZED has not forgotten that the first function of food is to appeal to the taste-nerves. ZED does—most emphatically!

To enable you to prove this to your own satisfaction, as well as that of your patients, we will be glad to send a regular sized package of ZED for trial purposes.

Feeding the Ailing Infant

PURE, plain gelatine added to the baby's formula, not only makes the milk more digestible, but it also increases the nourishment obtainable by about 23%, according to the standard feeding tests conducted by Dr. T. B. Downey, Fellow at the Mellon Institute, University of Pittsburgh.

This addition of Knox Sparkling Gelatine to the milk diet is particularly recommended where infants are suffering from malnutrition, indigestion, regurgitation and vomiting, curdy stools, diarrhoea, constipation, colic or excessive gas formation.

Here is the most approved method of modifying baby's milk with gelatine:

Soak for ten minutes one level tablespoonful of Knox Sparkling Gelatine in $\frac{1}{2}$ cup of cold milk taken from the baby's formula; cover while soaking; then place the cup in boiling water, stirring until gelatine is fully dissolved; add this dissolved gelatine to the regular formula.

For children and adults, follow the same method, but in the proportion of $\frac{1}{2}$ teaspoonful of gelatine to a glass of milk.

In infant feeding the gelatine may be added to any regular formula prescribed by the physician.

To safeguard against impurity and disturbing acidity, it is essential to specify Knox Sparkling Gelatine, the Highest Quality for Health.

The physician's reference book of nutritional diets with recipes will be sent free to physicians or hospitals, upon request, if they will address the Knox Gelatine Laboratories, 417 Knox Avenue, Johnstown, N. Y.

NOTE:—From the raw material to the finished package, the family of Knox takes pride in producing the highest quality of Gelatine.

Philadelphia and London: W. B. Saunders Company, 1925. Cloth, \$10 per volume. Sold by Subscription.

Modern Surgery, General and Operative. By J. Chalmers Da Costa, M. D., LL. D., F. A. C. S.; Samuel D. Gross, Professor of Surgery, Jefferson Medical College, Philadelphia. Ninth edition, revised and reset. Octavo of 1527 pages with 1200 illustrations, some in colors. Philadelphia and London: W. B. Saunders Company, 1925. Cloth, \$10 net.

1924 Collected Papers of the Mayo Clinic and the Mayo Foundation, Rochester, Minnesota. Octavo of 1331 pages, 254 illustrations. Philadelphia and London: W. B. Saunders Company, 1925. Cloth, \$13 net.

New and Non-official Remedies, 1925, containing descriptions of the articles which stand accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1925. Cloth. Price, postpaid, \$1.50. Pp. 461+XL. Chicago: American Medical Association, 1925.

New and Non-official Remedies is the publication of the Council on Pharmacy and Chemistry, through which this body annually provides the American medical profession

with disinterested critical information about the proprietary medicines which are offered to the profession and which the council deems worthy of recognition. The book also contains descriptions of non-proprietary medicines which the council considers worthy of consideration.

In addition to a statement of the actions, uses and dosage of each product, many of these are arranged in classes, and these classes are introduced by a general discussion of the group; thus, the silver preparations, the iodine preparations, the arsenic preparations, and the biologic products are preceded by a thoroughly up-to-date discussion of the group.

A glance at the preface shows that, in addition to the description of the new drugs which were accepted during the past year, the book has been extensively revised; many of the preparations listed in the previous edition have been omitted and the statements of the properties of others have been revised to bring the descriptions in accord with present-day knowledge. Of particular interest is the revision of the general articles; thus, the article on endocrine products has been entirely rewritten to bring this chapter in accord with the series of articles on glandular therapy which were published in 1924 under the auspices of the council. A general article on medicinal dyes has been added.

A section of the book (brought up to date each year) gives references to proprietary articles not accepted for New and Non-official Remedies. This list, in conjunction with the book proper, constitutes a cumulative index of proprietary medicines which physicians may consult when some proprietary product is brought to their attention.

Physicians cannot dispense with the newer remedies that are being brought out, yet they can neither judge them on the basis of the manufacturers' claims nor have they the opportunity or time to determine their merits. For this reason every physician should possess a copy of the annual volume of New and Non-official Remedies which the Council on Pharmacy and Chemistry puts at his disposal.

Industrial Poisons in the United States. By Alice Hamilton, A. M., M. D., Assistant Professor of Industrial Medicine, Harvard Medical School, Boston, Mass.; formerly Special Investigator of Poisonous Industries for the U. S. Bureau of Labor Statistics. New York: The Macmillan Company, 1925.

Newer Methods of Ophthalmic Plastic Surgery. By Edmund B. Spaeth, M. D., F. A. C. S., Major M. C., U. S. A. Chief, Eye Clinic, Walter Reed U. S. Army General Hospital, Washington, D. C.; Clinical Instructor and Assistant in Ophthalmology, the Army Medical School, Washington, D. C. With 168 illustrations. Philadelphia: P. Blakiston's Son & Co., 1012 Walnut street.

Keeping Faith With Your Patients

Why do people choose you for their physician from among thousands of other professional men? Is there a difference in professional ability? Isn't it because they have faith in your proficiency; because they have been told how you benefited others; or—in plain language—because you are known as a better doctor?

If that be granted, then wouldn't it follow logically that our own increasing clientele among eye specialists is by reason of superior work and service? The growing faith in our work, our service and our policy can hardly be due to price, for we don't do work on a price basis. Nor can it hardly be due to using only high quality materials, for others may buy from the same manufacturers. *No, such success must consequently be due to all of these things plus the particular class of service that we render the professions.*

Therein lies a difference in our work and in our policy of absolute protection to you and to your patients, which distinguishes us from other optical houses. A difference which provides the only sure means of keeping faith with your patients, and a difference which from all indications must be overwhelmingly in our favor.

RIGGS OPTICAL COMPANY

SAN FRANCISCO - SANTA ANA - OAKLAND - LOS ANGELES

Other Riggs Houses are located at Appleton, Boise, Butte, Cedar Rapids, Council Bluffs, Denver, Fargo, Fort Dodge, Great Falls, Green Bay, Hastings, Iowa City, Kansas City, Lincoln, Madison, Mankato, Oklahoma City, Ogden, Omaha, Pittsburgh, Pocatello, Portland, Pueblo, Quincy, Reno, Rockford, St. Paul, Salina, Salt Lake City, Seattle, Sioux City, Sioux Falls, Spokane, Tacoma, Wichita and Waterloo.

Radium and Oncologic Institute

1052 West Sixth Street

LOS ANGELES

RADIUM THERAPY

An adequate quantity of radium and complete emanation apparatus affords the facilities essential for modern technique in radium therapy.

DEEP X-RAY THERAPY

Two complete 300,00-volt installations providing every facility for preliminary and post-operative Radiation and X-ray Therapy alone or in combination with other treatment.

X-RAY DIAGNOSTIC LABORATORIES

Completely equipped offer the profession every assistance for roentgenology as an aid in diagnosis.

HOSPITAL AFFILIATIONS

Including a complete high voltage X-ray and Radium Therapy department in the Methodist Hospital amply provide for cases requiring hospitalization.

LABORATORIES

Affiliated for clinical and pathological study and complete facilities for Actinic Ray Therapy.

This institution possesses unexcelled facilities for radium and radium emanation therapy and high voltage X-ray therapy. With modern X-ray diagnostic, clinical and pathological laboratories, complete equipment for electric coagulation, cautery and allied surgery, it offers the medical profession unexcelled facilities for the diagnosis and treatment of neoplastic diseases.

We desire to confer and co-operate with the Medical Profession in the treatment of cancer and other appropriate diseases and request inquiries either in person or by correspondence.

J. W. Warren, M. D., Roentgenologist

E. D. Ward, M. D.

REX DUNCAN, M. D., Medical Director

Antagonistic Action of Posterior Pituitary Extract and Insulin—From work performed on diabetic patients, Robert C. Moehlig and Harriet B. Ainslee, Detroit (Journal A. M. A.), believe that pituitary extract injections improve the muscular asthenia to a great extent. This is true despite the fact that the patients, for the purpose of the work, are not placed on a diet. Patients with hypopituitarism suffer from asthenia, and fatigue is easily induced. The opposite is true in cases of hyperpituitarism. Posterior pituitary extract injected into normal rabbits produces, as a rule, a slight rise in blood sugar. Posterior pituitary extract, when injected simultaneously with insulin, prevents the fall produced by the latter. Posterior pituitary extract, injected during insulin hypoglycemic convulsions, produces a rapid rise in blood sugar, with subsequent recovery of the rabbits. The point of attack of the pituitary extract seems to be in the periphery: viz., the skeletal muscle metabolism.

Quality of Nitrous Oxid Manufactured in the United States—G. W. Hoover, Washington, D. C. (Journal A. M. A.), reports on the investigation of nitrous oxid made by the bureau of chemistry. The survey of this industry included an examination of raw materials, the collection and examination of representative samples of the gas as found on the market in different sections of the United States, and interviews with surgeons, dentists, and anesthetists. The findings, though gratifying in the main, show the need for a close and continued watch over the quality of nitrous oxid being marketed. The production of this important anesthetic in the United States is in the hands of comparatively few manufacturers. It is a highly specialized industry, and there is every reason to believe that safe nitrous oxid is being marketed. This conclusion was borne out by the present investigation of representative samples. It is particularly gratifying to the bureau that none of the samples examined contained enough impurities to warrant action under the Food and Drugs Act. While a few samples showed the presence of perceptible traces of nitric oxid, none contained harmful quantities.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.
2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.
3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.
4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.
5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

SOME MEDICAL CONVICTIONS AND MEDITATIONS *

By GRANVILLE MACGOWAN, *Los Angeles*

THIS year your president will be satisfied in directing your attention to a few subjects with relation to our internal affairs, our life as a medical body, which he believes are worthy of your attention:

Permanent quarters for the California Medical Association; attitude of the profession toward what constitutes the practice of medicine; problems of industrial medicine; progress in the treatment of internal diseases; the Eighteenth Amendment; Revenue Act of 1924.

chimerical—stand fast; be true; be watchful. This country is one of party government. If the salvation may not be found in one or other of the two older political parties, then it will not be found outside of them. It will not be found in Communism.

This year your president will be satisfied in directing your attention to a few subjects with relation to our internal affairs, our life as a medical body, which he believes are worthy of your attention.

We are gathered here today in this beautiful valley of the Yosemite, the wonders of which were first portrayed to the world by an humble medical man, serving in a semi-military capacity. As we look about upon waters, cliffs, the great forests and the lush grasses of the meadow land, we awaken to the fact that we are isolated from the great cities—away from the hum of trade—we are in the country, where we can relax and enjoy ourselves and breathe the pure air. How many of you think that it would be delectable to have our own place in the country—to have a home to which we could go, where we would be free for a season each year from the inroads of the outside world—where we could be among ourselves, and have a place that belongs to us, which might be used by ourselves during our lifetime and kept intact for the benefit of the California Medical Association for many decades—a place of recreation and a place where we could hold our meetings and transact our annual business away from the hurry and crowding of our busy marts? There is among us one man—a marvelous business man for a physician, one who thinks of the comforts of the individual members of the California Medical Association—one who thinks in terms of the welfare of his own local society, and who has by precept and example and by persuasive ways built up the personnel of the Los Angeles County Medical Society. Dreaming of a home, an abiding place for this county society, when we did not have a dollar for it, he has today very nearly approximated the ideal which he set out to attain, and in this he has had pretty nearly the united support of the members of his society. He has dreamed further—he is still dreaming. We do not care to wake him up, because we wish to see his dream come true. He has interested with him a number of the far-seeing men of the association who desire to secure, at some convenient point in this state, both for those who live in the northern section and those who inhabit the southern portion, a place where we may have our home—a reasonably large place, either with a beach that belongs to us, or woodland with flowing streams, where we may live in tents, where we may have a simple and capacious hall, to which we can invite learned strangers to give to us, while we are entertaining them, some of their precious knowledge—not in a hotel, nor in some caravansary, but in some home of our own. Your President thinks that this is a very vital thing for the welfare of the California Medical Association, and he recommends that each member talk and work towards its achievement.

ATTITUDE OF THE PROFESSION TOWARD WHAT CONSTITUTES THE PRACTICE OF MEDICINE,
WHICH IS GREATLY CHANGED FROM WHAT IT WAS FIVE YEARS AGO

Believing as we did when an organized effort was made to cheapen the profession of medicine and lower the standard of the preparation required, in the struggle for the protection of the interests of the

* Address of the President of the California Medical Association, Yosemite, May 18, 1925.

people, such as we understood it, we sought to control political opinion in two bitterly fought campaigns, and in the end we lost our battle, and we lost it for two very potent reasons—one, because there is a very large Pharisaical element among us, an element so greatly impressed by its own present social and professional perfection that it feels its own professional interests to be entirely protected by its intellectual superiority, and that it is not incumbent upon it to guide or influence the public in general for the public good. The second reason was the unwillingness of the average practitioner of medicine to assess himself to pay for the prevention of the success of the chiropractic and osteopathic bills. These latter groups, being well supplied with money and the enthusiasm of the forbidden, gathered up their votes and put their measure through. So we are today living in a regime of medical freedom in California. No one knows exactly what constitutes medical practice; it is not definitely and succinctly defined. Apparently, under present conditions anyone can, without legal danger, prescribe for the sick. The public is beginning to grow into the position where it makes no definite distinction between a learned physician who has with great care and sacrifice of time and money attempted to perfect his art and the charlatan who had never seen the inside of any real medical school, nor listened to the teaching of any real physician. We have, as a body, to a large extent taken the position of our Pharisaical friends, that this is a question which concerns the public itself. Thus we have, as a body, while waiting, unwillingly and with grumbling, accepted the lowering of medical standards. As individuals, some of us have not felt like adopting this attitude. Although the public has shown very clearly by its votes that it does not desire our assistance, yet we have believed that, perhaps, the populace will presently awaken to the errors into which it has fallen, so that in matters of public health, through the League, we endeavor by persuasion and indirection to render the opposition as innocuous as possible, and we hope to accomplish by education, through our organ *Better Health*, which is now a regular journal to be found on all news-stands, what we failed to do by strenuous political combat.

THE DISSENSIONS IN OUR RANKS, BECAUSE OF
THE PROBLEMS OF INDUSTRIAL MEDICINE,
STILL SEETHE

There is much dissatisfaction as to the present condition of the enforcement of the medical side of the Industrial Compensation Act in the state of California. This is again a question in which the interests of the working man and of the physician are pitted against those of the employer and the insurance carrier, and its intricacies are such that it is very difficult to understand and perhaps even more to alleviate. The attitude of some of the members of the association in this matter is very far from ethical, but it appears to be within the law, and if we do not like it as it is, our remedy is to have the law changed, because this association does not, as a few of its members seem to think, possess any dictatorial power as to who shall be employed upon the panels, or to designate when and how injured people

GRANVILLE MACGOWAN
President C. M. A. 1924-1925

shall be looked after. This brings us around again to the question of attaining sufficient political power, as individuals, to have attention paid to our requests as a body. It is in this way, and this way only, by indirection, that our influence may be felt by those who make and those who enforce our law.

We have at the present time a Committee on Industrial Practice which, under the chairmanship of Dr. Hyman, has a plan which your president believes will get you somewhere, if you adopt it. But this plan requires the action of the medical men interested in industrial medicine as a unit, and if there are not too many among you unwilling to deprive yourselves of the pleasure of finding fault and to learn to program for the general good, or if there are not too many Brookharts or La Follettes in our ranks, there is a good chance that this matter will be settled, perhaps, some time before the youngest member of the association dies, should he live out his life expectancy.

It is a common saying, said so many times that it almost becomes trite, that there has been little progress in the medical treatment of internal diseases, as compared with the great changes wrought in pathological conditions which are amenable to the interference of surgery. But this only appears more striking because it is more spectacular.

To the genius of Louis Pasteur, who was only an honorary doctor but the most marvelous chemist of all time and the best friend medicine ever had, our profession owes its ability to accomplish its surgical miracles. It is he who made it safe to change the human frame by alteration, and to mend and darn its tissues without fear of infection and death. If

the mechanical skill is sufficient and enough care is taken to ascertain before operation that the subject has a reasonable metabolic index, marvels may be done in a surgical way, almost without any mortal risk, which were entirely impossible before the era in which the development of the twin sciences of stereo-chemistry and bacteriology were given to a skeptical and not very willing medical world. The research work of this school has in the last thirty years resulted in the discovery of a number of relatively specific remedies which are the pride of our professional life—antitoxin, the active agents of the pituitary and thyroid, and many others.

Along the lines of chemical research, following up the possibilities of the action of the dye stuffs as therapeutic agents in bacterial diseases, worked out chiefly by Ehrlich, Raisus and the Brady Urological Institute, we have been furnished with remedies which makes the life of a properly educated physician of today one of not only great value and usefulness, but also one in which he may feel very proper pride, because although he may not be able to conquer, overcome and heal each and every disease to which the human frame is liable, yet so much has been accomplished and the amount of guesswork so greatly reduced, that modern scientific medicine has much more to it than a college yell.

Many preparations introduced with fervor have fallen by the wayside through the premature claims of those who have discovered them, they not being satisfied to apply, as did Pasteur always, the rigid proofs which were necessary to convince the scientific mind which should always be ready to criticize its own work as freely and as harshly as it criticizes the work of others.

It has been rather well known for a number of years that colloidal preparations of certain metallic elements other than arsenic and mercury have a very active therapeutic influence upon bioplasmic changes. An English syphiliologist, a man of very great ability, introduced into medical practice quite a few years ago a preparation of colloidal sulphur which appears to possess to a considerable extent the power of causing the oxidation of minerals retained in the organs of the human system. MacDonagh firmly believes that intramuscular injections of this substance in those cases of syphilis which obstinately refuse to improve beyond a certain point under mercury or arsenic in any form will, after the moderate use of intramuscular injections, become once again susceptible to the therapeutic action of the luetic trinity of mercury, arsenic, and bismuth. The proof of this has never been sufficiently and accurately demonstrated, for these injections are, in most instances, extremely painful and patients often refuse to continue them sufficiently long to decide their value. It was noticed very recently, I think, purely empirically and perhaps accidentally, that in those cases of syphilis in which there are dermatitis of arsenical origin, they can be overcome or prevented during the prolonged use of arsphenamine or neoarsphenamine by the intravenous use of solutions of sodium thiosulphate, a preparation of sulphur which acts as a colloid. No danger apparently follows these intravenous injections, and it is believed and is reason-

ably probable that the presence of the sulphur in small amounts in an assimilable form causes oxidation and disappearance of the minerals which are, after long-continued use, deposited in the internal organs of the body. We furnish an agent that is lacking in the system, and in its presence the surplus of these other minerals is disposed of by the bio-chemistry of the body.

The latest addition to our pharmacopeia is the use of hexyresorcinol for renal suppurations. This preparation, we have found in my office to be very potent, and it looks as if Doctor Young's claims are well founded. This is really only another form of colloidal sulphur. There is no reason why the physician should rest under the imputation of practicing the science of medicine by guesswork alone. It is true, after all, that the chief thing which marks the great physician from those whom he works beside, is the knowledge of human nature—the ability to inspire hope and to drive away gloom and fear. But in addition the psyche must be assisted by some remedies which actually have therapeutic potency and furnish elements much needed by the human laboratory. It is certain that within my lifetime, the number of those remedies upon which we can really depend for relief of our patients in their illnesses has been marvelously increased. The chemist is always on the watch.

There is a subject of general interest—I might almost say of paramount interest—at the present time in the United States which I desire to bring before you. It is one that I approach reluctantly and more or less with timidity because I feel that what I am about to say may perhaps offend some of those whose opinion I value most highly, but nevertheless I cannot see, without protest, our great profession lending itself to what appears to be a civic wrong, the results of which are grave now, and give promise of becoming extremely iniquitous and perhaps disastrous to our nation.

A few years ago, by a combination of well-meaning fanatics, with heartless industrialists whose sole god is that of money, the celebrated Eighteenth Amendment to the Constitution of the United States was put over in the absence from the country of approximately four million young men who were voters. The fanatics, some of whom with most virtuous intent, thought they were acting for the best interests of the rising generation; others, professional uplifters, swayed by the hope of gain and the itch to pose as reformers and to have their names continuously blazoned in the limelight of the daily press, by assiduous work at the polls, often by measures of duress in their dealings with legislative bodies which, if employed for the passing of ordinary bills, would have been regarded as criminal, contrary to public policy and probably punishable by sentence to jail, passed the amendment and a glorious jubilee was announced. The method was rotten, but many believed the end justified the means, and that alcohol once removed from the market place and made difficult to obtain for any purpose and impossible to obtain for beverage purposes would prove to be a great saving influence upon those who had never

been subject to its use, and that crime would be definitely decreased and poverty abolished.

The alliance made with many great employers supplied the money needed for this object, and also in no way decreased the political power necessary to sway the legislatures. Many of us who were not naturally pessimists but inclined to optimism believed that perhaps the demon rum would be permanently abolished and that the high hopes of the advocates of total prohibition would be realized. The governing bodies of many medical associations voted upon this bill approved it and gave it their sanction. But alas! we knew but little of the temptations that such a law would present to those whose duty it became to enforce it. We had no idea of the enormous leverage which it gave to blackmail. We did not understand that so many young men of great physical courage, taught by the war to delight in adventure, would take up the trade or profession, more or less openly, of smuggling and manufacturing intoxicating alcoholic drinks and their distribution in cities, towns, villages, and rural districts. We had no means of knowing how shrewd, unscrupulous business men, forming combinations with courageous, fearless and murderous banditti, would let loose upon us a perfect flood of vilely concocted alcoholic beverages manufactured in Europe or in adjacent countries, inundating our seaboard and flooding the lands nearby our national borders; nor could we foresee to what extent, through connivance with national, state, county, or city officials from one end of this land to the other with these dealers, no one who has the price anywhere from Maine to California, from Canada to Mexico, need be without alcoholic drinks if he has the will to have them.

Gradually the morale of our peace officials has been undermined by the temptations to which it is subjected, so that today the surest way to obtain liquor which is measurably fit to drink consists in forming an indirect alliance with those who are named by the national and local authorities to enforce this law. In witness whereof, we have in the last three years, week after week, seen the dismissal of prohibition officers, policemen, sheriffs, and constables, and in many instances these forlorn individuals who have fallen under corrupt influence set in motion by the Eighteenth Amendment have been committed to the national penitentiaries for a crime which found its excuse only in the fact that "everybody was doing it."

Within these three years I have traveled very extensively in the United States. Nowhere have I seen among the kind of people with whom I would naturally come in contact, and who are exactly the same kind of people who are present here at this gathering, in their houses, in their clubs, and in their learned societies, any absence of alcoholic liquors, the supply of which was unquestionably, in the majority of cases, of illegal origin.

It has been my privilege to attend many social gatherings and often my painful experience to notice the character of drinking that exists among the sons and daughters of the well-to-do—in the dances, private or public, in the country clubs and places of

amusement, where boys think it smart to have a flask upon the hip and to use it and offer it to the young girls. And many of the girls themselves have these flasks which are also filled and used. It scarcely requires such observation, because every department store in the land, every dealer of silverware, every druggist, exhibits a vast number of flasks for the holding of illicit liquor to be taken to gatherings where the law may interfere with its being served openly.

At this time our government is engaged at sea in what is practically a civil war for the prevention of smuggling of alcohol—a civil war in which the navy and army are employed for the enforcement of the law; two bodies in which the sentiment, from the highest official to the most recently enlisted man, is almost totally against prohibition and from which it is idle to expect a heart-stirring enforcement.

It is true, or seems to be, that there is less public drunkenness; it is true, or seems to be, that the working class, the mechanics and the day laborers have more money for their families, because the price of alcohol is beyond many of these men, but so high has the daily wage risen in the last five years in America in the building trades especially that, I am told by employers, in many of the shops and factories of the land the bootlegger is a well-recognized individual within their walls and one whom it is impossible for the employers to expel without danger of incurring trouble with their discontented working men who, deprived of their really comparatively innocuous drink of mild beer, feel that their government is not one that cares for the welfare of the working man or his comfort and that they are not on an equality with the rich, who are able successfully to defy the law which bears the name of Mr. Volstead.

This has gradually given rise to an attitude of receptivity by these men to the doctrines of Communism, the agents of which are extremely active, and lose no time in fostering this discontent and sowing in this fertile soil the seeds of trouble.

I have no patent to advocate. We cannot return to the old order of things. The open saloon was a horrible political evil and should not under any circumstances ever be restored. But an iniquitous enactment, as is this amendment, which has made so definite a class distinction in our daily life, and so potently sows the seeds of discontent among the proletariat, and fosters pernicious habits among those who, by reason of their education and social position, will, in the next generation, lead in government and business and installs hypocrisy as a constant feature of our daily life, opens the way wide and full to the encroachment upon our personal liberty by other sumptuary laws, which the cruel Loyolas and Torquemadoes, the austere Albigenses, and the grim and merciless Puritan Sam Parris' witch burners, who exist all around us today as full of zealous and inhuman fanaticism, as ready to satisfy their sadistic natures as they did in the seventeenth century, would make use of every other dear-bought right which we have under our constitution.

While we seem to do the working man good by removing from him the opportunity at will to become a drunkard, we have offset this by the gradual

undermining of our civil honor and respect for law because we lead in our lives a continuous lie and will eventually lose the power of speaking the truth on any matter, and while we count the additional dollars in our savings bank, we forget it can be but little benefit to the individual or to the nation to gain a whole world and to lose its soul.

Now I say, gentlemen, that in the medical conventions which I have attended in many different cities of the Union, in the labor conventions, the proceedings of which I have been familiar with by reason of affiliated interests, in the political conventions of all parties in all parts of the country during the past three years, there has been no end of the supply of liquor that might be used and most of it illegally obtained; and I have noticed among our own people many drinking whom I know I never saw drink before in the old days.

We should not behave towards this very important question as if we were congressmen, because our opinions should not be throttled by the fear of punishment at the polls by the active minority. We should at least be able to say that our lives and actions are an example of our preaching!

I do not recommend and I do not ask that any official action be taken by our association, but I hope that each member shall go home and, in meditation, take earnest communion with himself to determine if the cause of prohibition is worth the price which we are paying.

And finally I have another subject which should be of great interest to you and of great interest to any learned body, the members of which gather together for the sake of improving their knowledge and skill in their respective professions from time to time in conventions held at some distance from their place of residence. You who make income-tax returns have learned with distaste and disgust within the past year that no allowance is made by the bureaucrats in charge of the levying and collection of the income tax for the expenses incident to the attendance of such conventions. The ruling of the department has been that those who are engaged in trades or business should have a per diem for their expenses while away from their homes in attendance on such conventions and for the actual transportation charges, but this is not allowed to doctors, lawyers or architects and several other professions, whose gatherings are looked upon by this department as intellectual junkets, pleasure trips, or social relaxations having no value near or remote to the government.

This ruling of the department incensed your president, and he has been largely influential in having your executive council instruct our attorney to draw up a law to be brought before the next congress for the removal of this defect. Your officers will endeavor to secure the co-operation of every incorporated society of regular physicians in the republic. The law is so drawn that it will cover the same question in meetings of other learned associations.

Following is the law:

Amend Section 214 of the Revenue Act of 1924 (a) (1), as follows:

Section 214 (a). In computing net income there

shall be allowed as deductions: (1) All the ordinary and necessary expenses paid or incurred during the taxable year in carrying on any trade, business, *or profession*, including a reasonable allowance for salaries or other compensation for personal services actually rendered; traveling expenses (including the entire amount expended for meals and lodging) while away from home in the pursuit of a trade or business, *or profession, or in attending professional conventions of the profession of which the taxpayer is a member.* (The words in italics comprised the proposed amendment.)

I thank you for your consideration in electing me your president for the year 1924-1925 and for your kind consideration, rendering the filling of this office a pleasure instead of a task. I wish my successor as happy and as pleasing a year in office as I have had. His year cannot be so instructing as has been mine, for he has been familiar as a member of the council with the machinery required to keep the association's business affairs in function which I was not, and it is my humble opinion that it is from this body, the council, that presiding officers of the society should always be drawn.

Brack Shops Building.

The Use of Physostigmin in Abdominal Distention—

The use of physostigmin in abdominal distention was studied by Hayes E. Martin and Soma Weiss, New York (Jour. A. M. A.), in non-toxic cases in which abdominal distention followed laparotomy, surgical shock, early intestinal obstruction, or injury to the central nervous system, and in toxic cases, in which the condition was associated with peritonitis or general toxemias, such as pneumonia or long-standing intestinal obstruction. In every case various simple measures, such as gastric lavage, enemas, turpentine stipes and colonic irrigation were employed when distention occurred, and physostigmin was not used unless those measures proved ineffective, the purpose being to learn whether physostigmin is capable of relieving these patients. All the patients who received physostigmin were in a serious condition, and all manifested alarming symptoms. All of the sixteen patients embraced in the group of non-toxic cases of abdominal distention were completely relieved of this distressing symptom by the injection of physostigmin. The fifteen patients embraced in the toxic group were benefited but little or not at all. The results of these experiences indicate that the drug should be administered in doses sufficient to induce its characteristic therapeutic effect or until the occurrence of systemic actions indicates that the limits of safe dosage have been reached. Physostigmin is a useful drug for the treatment of abdominal distention in non-toxic cases, especially. It is less useful in cases of the toxic type. It has fallen into disuse mainly because of the employment of insufficient doses, partly, perhaps, because of the failure to distinguish the type of cases in which it is more effective (non-toxic type) from those in which it is less effective (toxic type). The effective dose of the salicylate or benzoate, in cases which do not yield to simple measures, is from 3 to 4 mg. (from 1/20 to 1/16 grain) injected intramuscularly. Such a dose may be repeated once after an hour if the first does not induce any systemic effects, and it may be repeated three times (at least) at intervals of three or four hours if there are no symptoms which indicate that its systemic effects persist. The general condition of the patient and his behavior toward the drug must be observed carefully and must serve as a guide for the repetition of the dose. The dose required for those patients who respond to simple therapeutic measures, such as rectal enemas, has not been determined.

Jud Tunkins says patent medicine ads are so attractive that it makes a man who has his health feel like he was missing something.—Washington Evening Star.

AS THE LAYMAN SEES US*

Cultural Education in Medicine, Specialism, and the Distribution of Physicians

By EDWARD N. EWER, M. D., *Oakland*

CULTURAL education in medicine, specialism, and the distribution of physicians.

Cold science, effective but not always convincing, has come into nursing and medicine, as sentiment has been squeezed out. It has been remarked that, in the beginning, medicine was all art and no science, while now we are trying to make it all science and no art.

MOST of us who have been practicing medicine for a considerable number of years are sometimes troubled at an apparent change from high regard to something like querulous criticism on the part of the public we serve. There is an impression that the esteem in which the medical profession was once held has suffered in recent years. We find laymen here and there addressing medical men on such subjects as *The Layman's Impressions of the Medical Profession*; *What Is the Matter With the Medical Profession*, and like topics.

Conscious of progress and rectitude, we wonder wherein we have fallen from grace. The passing of the old family doctor, revered in story and song, has been the regretful theme of addresses and writings until it almost brings tears to the eyes. Thus do the humanities tug at the heartstrings, and cloud the vision, till progress and scientific achievement are lost to view.

The office picture of the bearded doctor in midnight vigil at the cot of the dying child, hand on chin in troubled thought, doing nothing, but breathing sympathy, had a fine human appeal. Bring the scene up to date, and what would the picture be? White-garbed figures, an impersonal nurse or two, and aspiring needles ready to jab into the infant's spine—efficiency, action, but repelling, a life jerked back from the brink perhaps; but roughly. Cold science, effective but not always convincing, has come into nursing and medicine, as sentiment has been squeezed out. It has been remarked that, in the beginning, medicine was all art and no science, while now we are trying to make it all science and no art.

Those fortunate individuals who have been blessed with cultural influences in their early surroundings, and especially in their educational advantages, still make conspicuous successes by applying their science clothed with human interest and sympathetic concern. Do we wish to encourage this character-forming influence in medical training, or is the whole world becoming so materialistic it is not worth while? Can we be educated and neglect the humanities? It has even been said the quacks get closer to the people than do the physicians; though cultural training, Heaven knows, has nothing to do with this.

One professor of philosophy said: "The satisfaction that many of us laymen get out of going to quacks is, primarily, the comfort of being treated like men instead of like incurious animals. An intelligent layman, in impatience with what he calls the intellectual selfishness of physicians, has recently declared, 'quacks know men, but not medicine; physicians know medicine, but not men.'" Certainly the obligation rests with medical educators to do everything possible to prepare their pupils, to the end that the effect upon the public will enhance the prestige of scientific medicine. The individual graduates owe it to their profession to give careful thought to this phase of their contact with the world.

Dr. John J. Abel says: "There should be in research work a cultural character, an artistic quality, elements that give to painting, music, and poetry their high place in the life of man." A fanciful way of putting it, but it conveys the idea I have in mind.

The people get their misinformation about scientific research in devious ways. Much of it is furnished by the anti-vivisectionists and the other antis. Just now a sensational novelist has furnished a good dose of it in "Arrowsmith." Thousands are reading it and thereby doubtless getting very fixed ideas of the unworthiness of scientists in general. In this novel all the characters who are credited as true scientists are given rather unpleasant personal attributes. Gottlieb has no heart or sympathy, his experimental controls must be carried out relentlessly, whether a number of human beings are sacrificed in the experiments or not. Sondelius has a heart, but he is a sort of roughneck, boisterous, drunken, and obscene. Martin Arrowsmith could have been handled more gently, but scenes of drunkenness and gambling are introduced to mar his good life work. Terry Wickett is cynical and grouchy.

On the other hand, all the characters in the novel, like Tubbs and Holabird, who are given credit for any refinement at all, are made fun of and depicted as namby-pamby, pink tea scientists, using their positions for personal social advancement. One gets the impression that the collaborator of Sinclair Lewis, who furnished the medical stage business for the book, must be a misanthrope with an axe to grind because of experiences in the McGurk institutes of the country which have not been to his liking.

Garrison calls attention to the fact that the century which saw the beginning of scientific medicine "was the culmination of an age in which the Greeks reached a degree of civilization and a supremacy in

* Inaugural address as President California Medical Association, delivered at Yosemite, May 18, 1925.

EDWARD N. EWER
President C. M. A. 1925-1926

philosophy, lyric and dramatic poetry, sculpture and architecture, which has not been equaled by any people who came after them. Never before or since had so many men of genius, the contemporaries of Hippocrates, appeared in the same narrow limits of space and time. Hippocrates gave physicians the highest moral inspiration they have, and he crystallized loose knowledge into systematic science." Thus did a period, during which cultural knowledge reached its acme, bring about the very birth of scientific medicine, and provide it with a code of ethics, than which we have no better today.

Of course there has never been a time in history when medicine and medical men have been quite free from criticism, and their activities even caricatured. Perhaps our hypersensitiveness is bred of our irritation at the apparent lack of applause at the wonderful fruition of the years of *experimental science*. These years are few in number, compared with the centuries of study by *observation*, or as Claude Bernard called it, *passive science*.

In our strenuous efforts to bestow upon a more or less unwilling world the benefits of recent progress, we have interfered with the tranquillity of our smug parasites—those greedy pests that live on the fringe of decent medical society and at its expense. I refer to the myriad frauds which have wilted a little in the sunlight of our propaganda for reform. We cannot entirely destroy them. Each new discovery fertilizes them into rank new growth.

For instance, discovery of a few physiologically active glandular principles has stimulated the busi-

ness of marketing, through medical channels, most of the messy stuff in the abattoirs, which people could not in any other way be persuaded to eat. These endocrine vendors mix up glands and their principles like Hungarian goulashes, make them into tablets, and men who have spent seven years in medical college are expected to fall for this shotgun endocrinology.

We have killed about half the patent medicine evil and have made enemies doing it. At first the periodical and daily press were none too pleased with the decline in patent medicine advertising; but later they rallied to the cause of honest medicine, and now make valuable allies.

We have valiantly fought the cults and quacks and have been roughed a little. They seem to thrive on opposition, and if we turn away the spot-light they will die out or grow into something useful and be absorbed, as have their long line of predecessors.

At present, there are under discussion two other subjects closely related to each other, as well as to the attitude of public criticism. One is specialism, and the other the failing supply of rural physicians. Both these matters rest upon the functioning of inexorable economic laws, which no sudden action by organized medicine, examining boards, or medical faculties can put aside.

The subject of specialism has been attacked by many writers during the last few years. It is curious to note that all straddled the question. They expressed a general feeling that there was something amiss, but none condemned the general practice of medicine, and none had the hardihood to condemn specialism as such. There was much concern over the relationship between the general practitioner and the specialist, and this was shown in the titles of many papers. There was comment upon the arrogant attitude of many specialists toward the family physician. The fact that such attitude exists at all may show the approach of the saturation point in specialism. If certain specialists find it necessary to argue specialism to their clientele and others in season and out, not sparing unworthy criticism of those who work in wider limits, the inference is they are feeling the pinch of hard times.

The advantages of specialization are stated by L. F. Barker to be: "It increases productivity; facilitates the acquisition of accuracy, speed and skill; provides for a better distribution of tasks; economizes material equipment and mental energy; and accelerates discovery and invention."

Specialism in medicine is only response to the spirit of the times. The public is familiar with it in commerce and industry, and undoubtedly encourages it in medicine. This encouragement meets ready answer in our ranks, where mental and physical capacity are subject to variations the same as they are in a Ford factory.

Ultra-specialism, however, is of questionable value. It prevailed in Egypt four hundred years before Christ, when Herodotus, the historian, says, "Each physician applies himself to one disease only, and not more. All places abound in physicians." And yet in ultra-specialism the individual of average ability and the genius, alike, seem at present to find

fertile soil. The one content to drive one bolt in the human flivver, day in and day out, gains a proficiency and prestige denied him in the broader field; and the other, of great mind, concentrating a lifetime upon one line of endeavor, should be expected in addition to material success, to add something of discovery and invention to the total of medical knowledge. If he does not reach these heights, he wastes his talents in narrow specialism, and his life would have been better spent in the service of broader practice.

To those who are inclined toward general practice the situation need not be wholly discouraging. The field is and always will be open in villages and towns; and in every great city are to be found men with enormous general practices doing the best of work. Their success is based upon that soundest of foundations—service. These men recognize the necessity of specialists. They use them freely when the welfare of a patient depends, first, upon the expert use of some instrument of precision too infrequently used to warrant inclusion in their armamentaria; second, upon the exercise of skill in technique, only to be gained by experience with many patients of a particular type; third, upon laboratory work too time-consuming for them to undertake. They choose their specialists with discrimination, for their ability and for their broad-minded willingness to co-operate, and who dare say the patients' interests are jeopardized by passing through the hands of such a general practitioner?

It has been said, "Patients who independently seek the aid of specialists often make a mistake, and the tendency is to be deprecated." With certain modifications this is true. A clientele, all his own, is a tempting asset to many specialists, but this does not alter the basic fact that a broad survey by a general diagnostician is, in most cases, of paramount value to the patient. The ability to make this survey should be the aim of the general man. Perhaps it will mean, especially in cities, his evolution into what we call an internist. The internist now is really a sort of advanced general practitioner. He is the diagnostician and distributor for the other specialties, like the family doctor, but he enjoys the prestige of specialism, and is most useful in his broad field. However, there are signs of disintegration here, for we see his work undergoing subdivision of the ultra-variety, to make room for the electrocardiographer, the gastrologist, the allergist, and, very lately, the periodic medical examiner. The latter is a new and perhaps logical development in the attempt to keep some place open for the wise individual who wants to know which specialist he needs, if any. Seriously, we do not know how far specialism is going, but we do know that in the reasonable subdivision of labor, energy is conserved. If it goes too far, integration will begin, and proceed until the economics of the situation are satisfied.

The same melting pot of economic laws figures in the problem of the distribution of physicians. This is the most actively discussed subject in medical economics today. The failing supply of physicians has caused great complaint from the residents of many rural districts, and there have been demands for drastic relief measures. One of these was a bill

introduced in the Tennessee Legislature two years ago. It was entitled "The Abolishment of the Preliminary Board of Medical Examiners." This legislation was devised with the view of curtailing the length of time and expense required to get a medical license to practice; and its author believed its passage would cause more physicians to locate in the remote country districts. The bill passed both Houses, but failed to receive the Governor's signature. The same position is taken by Dr. Pusey, who believes that shortening the time spent in medical college would attract to medicine a type of individual who would be satisfied to take up the burden of country practice. If this were so, we ought to see the cultists avoiding the cities and flocking to the villages and cross-roads; but while short in knowledge, they are often long in business wisdom. The other side of the thesis is exhaustively treated by Mayers and Harrison in a report of The General Education Board in 1924.

There never has been great attraction in the hardships of country practice, and even twenty-five years ago many young graduates only took it up because of the crowded condition of the profession in the cities, and because of the common belief that a living could be gotten more quickly in the village communities. After a financial footing had been gained, and experience acquired, many left for the cities. After the war the movement was accelerated. Many medical officers recruited from the country never returned, as they had conceived new ambitions through experience in well-equipped hospitals, and through special training in army schools. Many of these entered the specialties of medicine, and have kept pace with their metropolitan confreres.

At the same time there has been a general movement, outside the profession, toward the centers of population. The farmer cannot keep his sons and daughters at home, and has trouble getting labor. Over 50 per cent of the country's total population is in towns of 2500 or more. From 1910 to 1920 the rural population increased only 3 per cent, while the urban population increased 26 per cent. This indicates where the work is, and there the physician will go. One author says: "The reasons why the country doctor will not stay in the country are these: the inadequate fees, the bad roads, the hard work, the lack of hospital accommodations, insufficient educational opportunities, but above all, the lack of loyalty on the part of his patients."

When trained statisticians and economists study the subject, the reason for the exodus of rural physicians becomes manifest. The following passages from Raymond Pearls' article are expressive: "It is apparent that generally the exodus in recent years of physicians from the rural locations has had associated with it a definite and marked decline in the per capital real value of farm property. In short, it is seen again that the behavior of the physician in the conduct of his affairs betokens a considerable degree of good economic sense. The physicians behave in the conduct of life about as any group of sensible people would be expected to. They do business where business is good and avoid places where it is bad."

"After a young medical man gets out in the

world and by hard experience learns economic wisdom, his behavior thereafter, relative to location, will not be different according to whether his education was expensive or cheap."

One of the conclusions of the General Education Board report is: "There is no validity in the view that the proportion of recent graduates settling in the rural locations is lower than the rural population has a right to expect." The Massachusetts Legislature ordered a report on rural health and medical service, and the Department of Public Health made a report in January of this year. Some of its findings are: "Unless the movement of the general population from the country to the city is checked, the economic factors will increase rather than decrease the inability of certain locations to support a physician. Less than 6000 of the population of Massachusetts is more than six miles from a physician. The physician's charge for a distant call, compared with garage charges for making the same trip, shows that the difference is less than the usual fee for the physician's house visit in his own village. This places no higher valuation on the time the physician spends on the road than if he were a taxi driver."

Many examples were found of lack of loyalty in supporting the local physician which was not based on his professional shortcomings. The farmer is not behind his city cousin in his belief in specialists, and he often drives thirty miles to the city for more expensive, but no better, advice than he could get at home. His faithful professional neighbor, good enough for the drudgery of night calls and emergencies, only gains his full confidence when he displays intelligence enough to go where the business is going.

It seems to me there is danger in this propaganda for lowering the standards of medical education. The alleged unfortunate plight of the rural dwellers makes good copy, and it is beginning to be exploited in the periodical literature. It is likely to have its effect upon state legislatures, already prone to dangerously weaken requirements for medical licensure.

Though the argument looked plausible at first, I have failed to find any data sponsored by trained investigators which affords proof that high standards of medical education are at all responsible for rural shortage of physicians.

A study of the exact situation in California, made by our own council or by the league, would be of value if the discussion becomes acute or menacing from the legislative standpoint. I believe such a survey would show conditions to be about as they are in Massachusetts.

In conclusion, it would seem that our public is critical, not because it fails to recognize the colossal advance in medical science, but because the upheaval has subtracted something from the sympathetic, personal contact, so satisfying in the past.

Attempts should be made to overcome this by bringing back into the education of the physician some of those subjects which were of old considered necessary in the equipment of the well-educated person, but which have been dropped as impractical in this business age. They have to do with what we call the art of medicine.

The education of the present fits the physician superlatively for his narrow specialty, but it is not education which commands instant and general recognition. He knows his own attainments and he puts a label on them: surgeon, internist, obstetrician, and he is recognized at his own appraisal, and that only. Most of those subtle influences which could bind him to the human interest activities, such as languages, history, art, music, poetry, and religions, are crowded out of the pre-medical years. Much of the great mass of technical detail which has taken their places is undigested, hence not available for the practical field worker, but most valuable to provide the necessary succession of research workers. The needs of these two classes—field worker and research worker—seem divergent, in that the fifty are being forced that the one may emerge in perfection. The fifty must deal with tried and proven methods for the cure of ills, and in addition must be made into attractive mold that public sentiment may be directed, and scientific medicine allure, not repel.

In spite of all, medical progress is unquestioned and unrivaled. As regards our relations with our disreputable camp followers, quacks, cultists, sellers of useless medicine, and the rest, we are warranted in feeling optimistic, and hope to be loved some day for these enemies we are making.

251 Moss Avenue.

Zinc Stearate Dusting Powders for Infants—The second report of the Committee on Accidents from Zinc Stearate Dusting Powders appointed by the Board of Trustees of the American Medical Association has recently been published. Copies of this report, with an appendix showing the opinions of thirty-four representative pediatricians on the therapeutic value of such powders, can be obtained on request. Address, Committee on Zinc Stearate Dusting Powders, American Medical Association, 535 North Dearborn street, Chicago, Illinois, enclosing a self-addressed, stamped envelope. There were reported to the Committee 131 accidents from the inspiration of zinc stearate dusting powders by infants. Twenty-eight of the victims died. The Committee conferred with representatives of certain distributors concerning the dangers incident to the use of such powders on infants. Following a meeting held at the headquarters of the American Medical Association, these distributors agreed to co-operate by adopting self-closing containers for the powders they distribute and agreed that cautionary labels are desirable. Opinions were secured from thirty-four representative pediatricians concerning the therapeutic value of zinc stearate dusting powders. Thirty-one believe that such powders have no advantage over other dusting powders, that they constitute a hazard to infant life, and that their use should be discouraged.

Pathology of the Hypophysis—It is evident from the seven cases reported by J. P. Simonds and W. W. Brandes, Chicago (Journal A. M. A.), that, with advancing age, in many persons the hypophysis undergoes fibrosis, and the body does not receive the normal amount of the secretion of this gland. Fibrosis of the anterior lobe of the hypophysis occurs with moderate frequency in persons past 50. This condition is apparently due to arteriosclerosis of the vessels of the hypophysis. The character of the lesion is such that it must interfere with the function of the glandular portion of this organ. This suggests one of the reasons for the failure of efforts at rejuvenation that are directed to the restoration of only one gland of internal secretion. One case of the series here reported appears to be true chronic hypophysitis. In spite of the negative Wassermann test, other findings in the body suggest the possibility of syphilis as its cause.

A GENERAL CONSIDERATION OF SUSCEPTIBILITY TO SKIN DISEASES *

By GEORGE D. CULVER, M. D., *San Francisco*

It rests upon the shoulders of the dermatologist to go more than skin-deep. Careful advice as to exercise, rest and proper eating will greatly improve oxygenation, raise the skin resistance, and often mean the deciding point between success and failure in the practice of this specialty.

WITH the large proportionate increase in infective skin eruptions and with recent added interest in occupational dermatoses, a vital question again and again arises as to how great a factor is the lowered individual resistance, permitting what would seem to be a fairly definite individual selection. The same question has to be considered in reference to many of the skin disorders.

If the presence of the streptococcus were all that is required to give rise to the numerous instances of streptodermitis, we should all have some form of streptococcic infection. We must assume that the sufferer has a lowered resistance or has something within his skin that makes of it a suitable soil for the rapid multiplication of streptococci. The eruption might indicate the presence of the organism in the lesion, or it might be an evidence of the toxic effects of its products. It would still mean something inherently wrong with the individual skin. This should hold true with most, if not all, eruptions caused by micro-organisms.

Furthermore, it isn't unreasonable to believe that something more than simple idiosyncrasy and natural susceptibility enters into dermatoses produced by external irritants. For example, many an individual may have worked at his occupation for years, and suddenly he becomes sensitive to something he is using, as a painter with his turpentine. It is occupational, yes, and seriously so, but it doesn't always mean that he must quit painting. Not infrequently there are other reasons than the known one for his hypersusceptibility. It is up to us, as dermatologists, to ferret out and correct such other faults as may be at the bottom of his recently developed susceptibility.

For a long time I have been attempting satisfactorily to solve some of the questions arising in many instances of eruptions easily diagnosed, but not always so easily eradicated, constantly striving toward more effective treatment, and also toward greater security in prophylaxis. Any evidence I may offer is so inconclusive that it is tendered only along the line of a suggestion to stimulate further observation.

Dermatology as a specialty, equal in importance to any branch of medicine, can hold its place and grow only as the dermatologist fulfills his mission of successfully treating his patient, not alone his patient's disease, and to do this he must have a clear conception of all the factors involved. It is my belief that a furuncle or carbuncle surgically treated, however skillfully, but with indifferent care given the patient himself, is neglectful ministrations. Much

dependence is naturally placed upon the inherent tendency for the human body to recover, and many an opportunity is lost when that tendency is not stimulated through proper direction in fortifying the patient's resistance to the particular disturbing element which may be specifically responsible for his disease.

It is this defective resistance that should be of such great interest to the dermatologist, and the neglect of which we all at times are guilty. Most satisfactory results often occur in stubborn skin eruptions, resistant to ordinary treatment, when a normal dermal physiology is brought about.

A certain proportion of the patients we see are either free from organic defects or are suffering little because of them if present, whereas but few are free from functional disorders. How necessary it is to recognize those functional disorders and to be able to so direct the patient as to correct them.

Consider, for example, the epidermophyton implantations which, with other fungus disorders, are increasingly numerous, making of every swimming tank a danger spot. And yet not everyone exposed is infected. Again, we may ask the question, Why? No doubt a disturbed physiology is frequently, if not always an important factor. If largely dependent upon an hyperidrotic base the factor may or may not be easily controlled, but it would seem to be our duty to make the effort, in justice to the one seeking advice to avoid subsequent reinfection. I have seen most dramatic changes take place in that tragic state of wet, putrid feet when excesses of eating, especially of the rich carbohydrates, were properly regulated and other faulty habits corrected. I am not contending that it is just a food question, but it must be admitted that in many instances of both acute and chronic skin affections there is something basically wrong with the skin activity, and what more likely than that it should be influenced by daily regime, including faulty dietary, neglect of exercise and irregular or insufficient rest, all of which may affect the body covering, as well as other parts, especially insofar as skin nutrition and oxygenation are concerned.

Examples innumerable, explanatory of my contention, may be cited, but they would be tiresome. I shall give only a few recent ones that were of particular interest to me.

A physician under 35 years of age came to me nearly a year ago with what was clinically an infective dermatitis, involving the face, neck, and arms to such an extent that he could not satisfactorily practice his profession. He had gone through a most careful series of tests for some specific element that might be the cause, and, though he reacted to a number of things, the blame couldn't be laid to any one. He suffered for two years. After treating him several months unsuccessfully he became discouraged and so did I. It fell to me again to attempt to advise him, and we started anew, just as if he were a patient for the first time. He was asked to follow a much more rigid daily routine of exercise, regular and sufficient rest, with carefully regulated meals. Internal medication was directed toward normal elimination, proper alkalization and improvement

* Chairman's Address, California Medical Association's Section on Dermatology and Syphilology, delivered at the 1925 Session in Yosemite, May, 1925.

in his general well-being. Within two months his skin was clear, and it remains so, but on the least provocation gives evidence that it is ready to again flare up. It was neither the arsenic nor the iron given him that caused the disappearance of the trouble—which also failed to be influenced by endocrine medication, vaccines, or x-ray. Recovery was probably due to systemic improvement through better general body tone and better physiological functioning of the skin, with a consequent raising of its resistance. This man had asthma, and this symptom also has disappeared.

In an instance of severe streptodermitis of the legs, which hospitalized the patient for the greater part of four years following the war, the condition entirely disappeared under careful routine directed toward raising the patient's general resistance, and simultaneously the resistance of his skin to the infection.

A young woman with recurrent generalized dermatitis, clinically of an infective character, who had been inadvertently treated for poison oak by many methods, gave evidence of harboring the streptococcus in her throat. Treatment for focal infection alone and symptomatic treatment of the skin proved quite discouraging. Not until the patient herself was considered of prime importance and treated accordingly was real success attained.

Because it is possible to do so much with the skin with the many varied and remarkable agents now at one's disposal to either cure or eradicate so many manifestations of skin disorders, and because the task of treating the patient is so difficult and so laborious, the tendency is surely toward a greater perfection of the former agents and methods, to the neglect of the latter important phase of the question under consideration.

I am not scolding the other fellow; rather my inclination is to chide myself for so frequently drifting into the easy way of treating the disease instead of the patient. Should a patient come to me with that most trying condition, acne rosacea, there is no hesitancy on my part as to what I must do, for I know that by treating the facial manifestation alone I shall partly or completely fail, and certainly not make the patient's future sufficiently secure, whereas by treating and directing him generally as well, the chances of success are greatly multiplied. My neglect in one instance was firmly impressed upon me by the patient himself, a friend suffering from psoriasis, whom I treated perfunctorily for his "spots," as did others of my confreres. About a year ago he developed a marked rosacea, which stimulated me to more carefully consider his condition. Under more careful treatment his rosacea disappeared, a glycosuria disappeared, and his psoriasis has become much more manageable. What a growing tendency we have to treat acne topically only, because of having such an excellent help as the x-ray. However, we owe it to the patient to do as much for him otherwise as he is willing to accept.

Within the last month a man 32 years of age consulted me for a recurrent infection in the right scrotal-thigh fold, covering a period of one and one-half years, involving part of the time the scrotum

and part of the time the skin of the thigh. There were abscesses and numerous ulcerations. He presented a marked acne rosacea of the middle portion of the face, gave a history and showed the scarring of an extensive acne of the back which had been present when he was then years younger, and the back of his neck was almost covered with scar tissue. This man for ten years had been treated while in college, later while in the army, and many times since, always locally alone, for the particular condition present at the time. It is quite evident that this patient was in need of a most rigid and systematic routine with the proper tonic and regulating medication to build up his resistance, which in the past had been improved only insofar as his natural tendency to recover counted, and as he grew older this resistance lessened rather than increased.

I am of the opinion that some of the endocrine instability which we find favoring skin changes, and much of that which we conjecture as a possibility, would be lessened or completely removed under improvement in the general well-being of the patient.

Since such a large part of a dermatological practice is made up of those not acutely ill and of those apparently able to work, the physician is inclined to pass lightly over skin eruptions and to send referred patients back with negative findings. Not infrequently those are just the ones that continue to have their skin annoyances until the basic functional disturbances are corrected.

It, therefore, rests upon the shoulders of the dermatologist to go more than skin-deep. Careful advice as to exercise, rest, and proper eating, will greatly improve oxygenation, raise the skin resistance, and often mean the deciding point between success and failure.

323 Geary Street.

Blood Pressure Changes Accompanying Coronary Occlusion—In the absence of hemorrhage, shock, infectious disease and excessive toxic or metabolic disturbance, such as diabetic coma, and with the presence or history of severe pain of cardiac origin or distribution, Leslie T. Gager, New York (*Journal A. M. A.*, June 6, 1925), says that the fall in arterial tension will commonly be due to acute myocardial insufficiency on the basis of coronary occlusion. Four cases are cited to show the value of a series of blood pressure readings, when coronary thrombosis is in question. Gager further says that: The recognition of a sudden fall in blood pressure, following an attack of severe cardiac pain, derives its importance from the fact that coronary occlusion brings about this state of hypotension by striking directly at the cardiac output. Following the thrombus formation, or the lodgment in an embolus, in a coronary artery, there occur (1) infarction of the heart muscle to a degree corresponding with the site of obstruction, and (2) impairment or loss of ventricular function according to the area and extent of the infarction. Since the left coronary artery, or its branches, is commonly involved, it is usually the greater circulation that offers the evidence of cardiac failure. In the milder instances of occlusion, or in cases in which the left ventricle escapes, little or no variation in peripheral arterial tension may occur. It is Gager's contention, however, that blood pressure readings, taken daily or even oftener, form an important detail in establishing the diagnosis of coronary occlusion. It is a method of observation at the command of every practitioner. A sudden fall in arterial tension, following severe cardiac pain, rests on the physiologic basis of infarction and myocardial insufficiency following an occlusion.

UNUSUAL UROLOGICAL LESIONS *

By FRANK S. DILLINGHAM, M. D., *Los Angeles*

Brief reports of three cases of fracture of the penis, one of priapism, one of anaphylaxis, and four of toxins from ascarides and oxyuris, causing hematuria and albuminuria.

FROM time to time we all see interesting and, sometimes, rare conditions which, through lack of time or inclination, are not reported to our local sections, or perhaps because of a feeling that the report would not interest a group of men practicing the same specialty; yet if briefly reported such rarities might call forth reports of similar conditions by others, and the discussion might bring out some practical points of benefit to all.

To successfully practice urology, it is necessary to have a broad knowledge of all the specialties. The increasing knowledge of anaphylaxis, referred pain and focal infections, have played their part in forcing us to look beyond our own field in arriving at a final diagnosis.

Last year we were told of a large railroad hospital in which every patient with abdominal symptoms was studied by the urologist before being subjected to laparotomy, with the result that there have been less abdominal operations, and the proper treatment of unsuspected urological conditions have permanently cured the patient.

As our program is very full, I will briefly report a few histories, and wish to add a case of priapism to those reported by two of our members, Doctors Player and Kutzmann, in the *Urologic and Cutaneous Review*, December, 1923.

Patients with arthritis are sent to us for study, and it is hard and sometimes impossible to give their physician a definite answer as to whether the urological tract may be at fault in the presence of a small soft prostate, with moderate infection in the prostate and vesicles, when there may be associated in the same patient beginning flat-feet, infections in tonsils, teeth, or elsewhere. An orthopedic surgeon referred a patient to me who had arthritis of the right hip which had progressed so far that they had to apply a Bradford traction and abduction brace and arch supports. This patient had been thoroughly studied and no foci found in the teeth, tonsils, intestinal tract, or elsewhere. His prostate was small and only slightly infected, and in my opinion was not likely to be the source of the patient's trouble, but as the usual foci were reported negative a thorough course of massage of the prostate, with stripping of the vesicles, followed by an antiseptic, was instituted and he fortunately responded at once. The patient is back at work as a cutter in a tailor shop, where his occupation compels him to stand all day. He has not had to wear the brace nor plaster cast since last November, but continues with his arch supports; he has no pain.

A woman, aged 39, complained of a burning pain in the urethra, was cystoscoped and carefully exam-

ined, but no cause could be found, and as a last resort skin tests were made and she was found to react strongly to coffee and eggs. As long as eggs in any form and coffee were omitted, she had no pain. Local applications of silver nitrate were made to the urethra and bladder neck, and at the end of a year she could gradually return to both coffee and eggs.

Several years ago a 5-year-old child was examined who had a history of hematuria and frequent painful micturition over a period of three weeks. The parents were alarmed and feared Bright's disease, as they could see blood and had been told the urine was loaded with albumin. Pinworms were discovered and their removal caused the bladder symptoms to abate, and the cystitis was cured in a week's time, with no return of symptoms, and the urine has remained free from blood.

Two years ago, in consultation at the hospital, I saw another patient with a heavy ring of albumin who was supposed to have Bright's disease. I was fortunate enough to enter his room as the nurse had finished giving an enema, and several round worms had just been washed out. Appropriate treatment of this condition cured the albuminuria. Last year another patient who had been in the hands of good physicians in Denver and Los Angeles, who had been cystoscoped and carefully examined to determine the cause of pain and throbbing in the urethra, and who received no benefit from treatment through the endoscope with silver, was found to have round worms, and treatment of this condition promptly relieved the reflex symptoms in the urethra.

A tape worm in a woman of 35 caused albuminuria and a dull ache in the kidney regions which was relieved as soon as the tape worm was removed.

Doctor Arthur Herrmann was kind enough to go over some of his histories for me and found three reports of worms in the bowels, causing frequent micturition, vesical tenesmus, blood and albumin in the urine, which were relieved in each instance as soon as the worms were removed.

"A girl, aged 7, had been suffering from digestive troubles and vesical tenesmus for several weeks; was taken suddenly ill with a slight convulsion. She had recovered from the convulsion before my arrival, was slightly delirious, and the temperature was 104. Urine examination showed albumin, microscopic blood, no pus or casts. There was no swelling of the extremities. A careful history elicited the fact that the child had passed some round worms and also pinworms a few weeks previously. The administration of santonin and quassia injections, together with a clove of garlic daily, gave prompt relief of all abnormal symptoms.

I was called in consultation to see a boy aged 3 in a severe convulsion which was abated with chloroform. He had been a vigorous child, but lately had become fretful, complained of abdominal pains and loss of appetite. There was frequent micturition, he wet the bed, was restless in his sleep, and lost weight. Urine examination showed albumin, blood, no casts or any abnormal findings. A close questioning of the mother brought out the fact that the child had passed some round worms a number of weeks

* Chairman's Address, California Medical Association's Section on Urology, delivered at the 1925 Session in Yosemite, May, 1925.

previously, and that she had given him some worm candy which caused the expulsion of several. The usual treatment by santonin was instituted and a large number of round worms were expelled; the urinary and all other disturbances were immediately relieved.

A girl, aged 4, was brought to the hospital, having been referred to me by the late L. M. Ryan, with a diagnosis of pyelitis. The chief complaint was frequent micturition, bladder tenesmus, loss of weight, and irregularly elevated temperature. Urine examination demonstrated B. coli, pus, blood, and albumin. There was intense itching of the anus and genitalia. She had been given the usual alkaline and urinary antiseptics which gave intermittent relief. The history demonstrated she had been troubled with pinworms irregularly for more than a year, to which the mother attached no significance. The child was placed at an angle of 45 degrees for twenty minutes, and once daily a solution of quassia bark was allowed to flow in the bowel. A clove of garlic was given in her food once or twice daily. The alkaline treatment was continued for the pyelitis and after several weeks the child slowly recovered, while the tenesmus, pruritus and excoriated genitalia cleared up within a week.

CONCLUSION

The chief interest in the study of these cases is the fact that the toxemia and urinary symptoms cleared up on the expulsion of the worms; that the toxic substances produced a renal irritation due to some secretion from these worms, that they cause a mechanical irritation which gives reflex symptoms to the urinary tract, adjacent tissues and cerebral cortex."

A patient with typical renal colic, whose x-ray plate showed an oval shadow in the region of the right ureter, could not be cystoscoped because he had filiform strictures. These strictures were dilated as rapidly as possible with a fairly prompt and progressive improvement in his renal symptoms, and when a shadow catheter was passed to the pelvis of the right kidney, the shadow proved to be a lymph gland, and this patient has had no more renal symptoms.

THREE CASES OF FRACTURE OF THE PENIS

A laborer, aged 28, said he turned over in bed while he had a partial erection. The rupture occurred at 5 o'clock in the morning and caused considerable pain, but he went to work. I did not see him until 5 o'clock that afternoon. The skin was edematous, infiltrated with blood from the root to the glans, and a distinct tear of the right corpus cavernosum was found .025 long. The clots were (2.5 cm.) turned out, hemorrhage arrested, fascia lightly sutured, four linear incisions the full length of the shaft were made through the skin on account of the excessive edema, and the organ carefully bandaged. The wounds healed by first intention, and the man made a perfect recovery, with no deformity.

A doctor about 30 years of age sustained a similar injury while climbing out past the steering wheel

of his car. He was seen within an hour. With careful bandaging and rest in bed, the clots were absorbed and there was no deformity.

A cowboy was similarly injured by being thrown on the pommel of his saddle. By using about a 20 gauge needle, we were able to aspirate the clotted blood enough to relieve his condition. This was followed by bandaging and rest in bed, and he was able to return to work in a week or ten days.

Priapism—During the late war a certain patient was gassed three times, which caused him to lose considerable weight. Throughout the war had chronic dysentery, and upon returning home an infected appendix and gall-bladder were added to his troubles. On March 20, 1922, the patient had a constipated passage which was immediately followed by pain in the perineum, to relieve which he made pressure over the perineum. This in turn was followed by a full erection, which was not relieved by hot or cold compresses, morphine or several other measures, and lasted for three weeks, at which time the erection gradually subsided. Full doses of epsom salts gave the most relief. When I saw the patient in consultation he was well nourished and has scar from his former appendectomy and cholecystectomy. General examination negative, with the exception of infected teeth and tonsils. Denies ever having had any venereal disease, and blood Wassermann was negative. Eyes and reflexes normal. No nasal polypi; no enlargement of the prostate gland, but the hemorrhoidal veins were engorged. Urination difficult, but not painful. Patient complained of being tired, even to exhaustion, partly from loss of sleep and partly from nagging pain in the penis and the anal regions.

The penis was erect, engorged, harder and larger than normal, the corpus spongiosum being involved, as well as the cavernosa. The testicles were normal, and the urine negative. There was no sexual desire; intercourse tried once, but was painful and afforded no relief and was not repeated.

I recommended that the teeth and tonsils have immediate attention. This was not done, and later, in connection with doctors of the Public Health Service, I saw the same patient suffering with a severe purpura hemorrhagica, and again recommended that the teeth and tonsils have immediate attention, beginning with the teeth. Upon examination, eleven teeth were found to be infected. These were removed one at a time, each extraction being followed by considerable general reaction, but this treatment eventually cured his skin condition.

As a result of the priapism, the patient has a loss of erectile power amounting to fully twenty-five per cent. He is still forced to wear elastic stockings on account of the edema in his legs, and is not able to work. Cause of his trouble is considered to be due to thrombosis, probably resulting from infection from the teeth and possibly tonsils.

Drainage of the corpora cavernosa in this case would probably have afforded immediate relief and would not have been followed by as much loss of erectile power.

SOCIAL ASPECTS OF THE FREE DISPENSARY *

By ROBERT EWART RAMSAY, M. D., Pasadena

The free dispensary, as a philanthropic institution, can not do otherwise than divide the applicants into two classes—those who can be freely treated, and those who cannot be treated at all.

Once the Social Service Department has ascertained the social status of the patients who wish to pay a small fee, and determines that they are worthy of some fee deduction, it can find physicians who are willing to handle these part-pay patients on a part-pay basis, without detriment to their established schedule.

There is none of us who will not co-operate in that wise philanthropy which increases self-respect and conduces to self-support. But undeserved charity breeds selfishness and pauperism in the recipient and wearies and disillusiones the philanthropic worker.

THE free dispensary exists to give aid to persons who are not able to pay the customary medical fees. Philanthropic individuals and associations give their means, volunteer workers give their time, and physicians give their professional advice and service. Superintendents, nurses, social workers, secretaries, clerks, and volunteers give very often more than the time of the working day. To all of these, but especially to the donors, the volunteers, and the physicians, it is a matter of great concern to know that the service they so freely give is bestowed upon persons who are needy and deserving. Physicians are especially concerned because it is manifestly unfair to be called upon to give advice without charge to persons who are able to pay.

The practical problem of deciding who are deserving of help is not difficult. Slipshod methods of administration have made it appear so, and sentimental considerations have undermined the morale and the efficiency of many a philanthropic institution. The public has little respect for organizations so easily imposed upon. Those who are helped call themselves clever in getting for nothing what others must buy, while the workers develop contempt for certain of their beneficiaries, or take the matter into their own hands by making unkind remarks or giving a lower type of service. If the problem is not faced squarely and decided on business principles, the right kind of work is not done.

Consideration of the actual conditions which arise in the conduct of a free dispensary will disclose the nature of the problem and show how it may be approached. For this reason I have reviewed the social records of 1384 consecutive admissions to the free dispensary of the Anita M. Baldwin Hospital for Babies, children's department of the California Lutheran Hospital of Los Angeles. The facts in these records were verified by home visits in practically all of these cases, the exceptions being those in urgent need and families manifestly large in numbers. I have also reviewed the records of 398 consecutive applicants who were referred to private physicians because, by their own admission, they were financially able to pay. Unfortunately, for the purpose of statistical comparison, this number does not represent the total number of persons who visited

the dispensary and were discouraged from entering, but only those who went far enough to have an interview with the social service department, with the end in view of establishing a satisfactory social status.

All applicants have been questioned on the day of admission with regard to sources of income, amount of average income by the week or month, regularity of employment of the wage-earner, number of children in the family, number of other dependents, and in the case of a woman who supports her family, as to whether she is divorced, deserted, or a widow. This interview is resented only by those who have come to the dispensary under a misunderstanding or with the thought of taking advantage of its charitable purpose. The social visit which is made to confirm the impression at the interview is never resented by the *deserving* families. Rather is it welcomed because, when they have told their story and welcomed the representative of the dispensary in their homes, they feel established in friendly confidence, entitled to aid, and free to seek from nurses and doctors solution of their various problems. The procedure is of great value in cases where families are staggering under burdens too great to be borne and there is help from other agencies than our own which can be mobilized in their behalf. Our own work depends so greatly on home conditions that the need for this friendly co-operation with the home is self-evident.

Subject to modification by extenuating circumstances, we have adopted an arbitrary standard of \$120 monthly income for a family of father, mother, and two children, making an allowance of \$10 monthly for each additional child or dependent. This figure has worked out well in practice. It is sufficiently low to indicate that we demand some evidence of thrift. It is sufficiently high to indicate that we do not expect abject poverty before we give our help. The time to give the help that counts is when people still retain their ideals and have not given up their ambitions for themselves or their children, in time of temporary embarrassment, or in cases of large families. Into our special problem, as we see it in Los Angeles, enters the frequent occurrence of the family which has come to this land of promise, exhausted its resources before getting fully established, and finds itself unable to afford accustomed comforts. This type of family is worthy of our best help and sympathy.

Large families are a factor in bringing patients to the clinic. The average family numbered between four and five members, the exact figure being 4.41. The results may be summarized in a more effective way as 575 families of three or less, and 909 of four or more. Simple increase in numbers must mean either a decline in the condition of living, or a dependence on friendly assistance, or an unusual exhibition of industry and thrift. Thus, we found one family of eight living in apparent comfort and even paying on a home on a budget of \$150 a month. Two families of fifteen members were found in clean and well-furnished homes. But, on the whole, simple increase in numbers, without the addition of unusual misfortune, is a factor in making friendly aid necessary.

* Chairman's Address, California Medical Association's Section on Pediatrics, delivered at the 1925 Session in Yosemite, May, 1925.

The care and illness of dependents is also a factor. When parents and children are just getting along, and an aged grandparent becomes ill, the family resources are strained to the breaking point. In twenty-two cases where families were living in their own homes, unusual circumstances, such as illness of the breadwinner or dependents, justified our extending aid. The same may be said of sixty-one families who were buying homes. In such cases, the families had cut down their margin to the quick in order to get their feet under them, and unexpected illness or lack of work found them temporarily bankrupt.

At times there appears in the clinic some person with furs, silks or jewels, disturbing to the morale of the whole establishment, the patients as well as the staff. Sometimes the disturbing person is not the parent, but some friend, neighbor or other philanthropic person who does not dress in a manner befitting her mission. Sometimes the finery is borrowed to bolster up the pride of the wearer who is making her first visit to a dispensary. It would be too easy to turn away the well-dressed and admit those who were poorly dressed. This is a method too commonly used in free dispensaries. It should be summarily condemned as a method which is inefficient and often unjust. Many who dress plainly are well able to pay, while others come in mistaken pride with all they have on their backs. A good social service department will use the best judgment possible at the time of admission and verify this impression by a visit to the home. Meanwhile, the workers knowing that they are being protected from exploitation, can be gentle in their criticism, and proceed with their work.

The automobile still spells luxury to our minds, and we become critical when we see patients arriving in cars. But much depends on the type of car and whether it is the property of the patient or belongs to a friend or neighbor who is helping out. Then, too, an automobile is a necessity to many kinds of workmen and tradesmen. Where the social service department finds that the automobile is of the type used for business and is owned and used for that purpose, we are charitable in our conclusions. When a family admits that paying for a touring car has diminished their ready money, we do not feel at all charitable.

A problem which frequently arises is that of the parent who comes to the clinic because she feels that she can get there the expert attention to which she has become accustomed but cannot now afford, and frankly explains that she can pay something and would prefer to be on that footing. To this admirable type of person it is not easy to give a rebuff, but the free dispensary, as a philanthropic institution, cannot do otherwise than divide the applicants into two classes—those who can be freely treated, and those who cannot be treated at all. It seems to me that once the social service department has ascertained the social status of the patients who wish to pay a small fee and determines that they are worthy of some fee deduction, it can find physicians who are willing to handle these part-pay patients on a part-pay basis, without detriment to their established schedule.

A periodic review of social status is necessary in

order to exclude those who, because of increased prosperity, have become able to care for themselves. This is accomplished in simple fashion by requiring patients to register anew every three months. This necessitates another interview with the social service department and a new establishment of status.

A review of the cases which were referred to private physicians shows that the dispensary must have an alert social service department to inform applicants with regard to the requirements for admission. Let us put it this way, rather than to speak of exclusion, for many people come to the dispensary because they do not know a better place to which to go, to get the type of service which they desire. There is considerable satisfaction in giving these people courteous treatment. If they are newcomers to this region and have no physician, they may be given a list of the attending staff from whom to choose one. Some persons are shocked by the necessity for social investigation, because they have confused public health activity and private philanthropy. There is some reason for their embarrassment because national, state, county and city health agencies which are striving to disseminate information, and so far as possible to give practical help by means of health centers, baby welfare conferences, and the like, do not and perhaps cannot do otherwise than to serve all who care to come. It is not difficult, however, to make applicants see the difference between a public enterprise and a private one. Especially is it easy for them to understand that physicians who give their time freely must be assured that they are not being victimized.

The 398 cases which were given a social service examination and refused admittance represent that portion of those who applied for admission who were not satisfied with the information given at the desk nor self-condemned by a comparison of their income and the purpose of the dispensary, and therefore put their case up to the management of the dispensary. Ninety-six of these had a monthly budget of \$150 or less which made them border-line cases, according to the number of children and dependents. Among the remaining 302 we found electrical engineers, school teachers, draftsmen, carpenters, bookkeepers, earning \$200 a month; salesmen, insurance agents and small business men clearing \$250 to \$300 a month; an oil-well driller making \$400 a month; a real estate agent who acknowledged \$500 a month; and a dentist admitting \$600 a month. Such cases illustrate the necessity for an efficient social service department. There is none of us who will not co-operate in that wise philanthropy which increases self-respect and conduces to self-support. But undeserved charity breeds selfishness and pauperism in the recipient and wearies and disillusiones the philanthropic worker.

In conclusion, we may say that the majority of the applicants for the services of our free dispensary are worthy of our aid. There is, however, a large number of applicants who are perfectly capable of paying their way, have no business in a free dispensary, and should be excluded. This can be officially done by the social service department after conference, followed by visitation.

TEAM WORK *

By ROBERT BURROWS, M. D., *San Francisco*

ALTHOUGH efforts to alleviate pain during surgical procedure were practiced from time immemorial, it was not until the time of Morton in 1846 that practical anesthesia became a reality. However vague and uncertain the efforts before that time, there is no doubt about the truly wonderful development of anesthesiology since Morton's previous work. Much further progress may be confidently predicted. The list of scientific investigators, chemists, inventors and physicians who have and are devoting their time and efforts to the development of better anesthesia is a long one. Along with progress in methods of eliminating or alleviating pain during surgical procedure has gone the marvelous development of modern surgery. Better anesthesia makes better surgery possible. The dangers attending surgery and anesthesia have been recognized and much has been done to overcome them, and work still goes on to lessen and avoid those that still seem unavoidable. It should be a matter of congratulation that the necessity of education in anesthesiology has been recognized and that courses are now included in most of our medical curricula. Education in this branch of medicine is as necessary and important as in any other, and unless we can appreciate the co-relation of anesthesia with other branches of medicine, our work becomes purely mechanical. The anesthetist must be trained as well as the surgeon, and by the proper training and co-ordination of their efforts good team work may be achieved.

The anesthetist should be much more than simply the one who administers a certain chosen anesthetic. His knowledge of medicine should be such that he would be considered a consultant before, during and after the operation. He should be able to evaluate the physical signs and symptoms, the laboratory findings, etc., so as to form an accurate opinion as to the patient's ability to take an anesthetic and the anesthetic required. It is the anesthetist who watches the general condition of the patient throughout the operation, and by the intelligent estimation of the condition institutes such remedial measures as may be necessary. That he must possess mechanical perfection in administration goes almost without saying, and in this connection we may well be grateful to those within our ranks who have devised mechanical means for the administration of anesthetics with certainty and precision, and these we should be familiar with, never forgetting, however, that a machine is still a machine and that the patient's condition is the final criterion as to whether the anesthetic is being delivered properly. Mechanical perfection is not enough. We must co-ordinate the mechanical part of administration with the known pharmacophysiological reactions of the anesthetic. All patients are not alike, and we must be able to vary our agents, sequences, mixtures, and amounts according to the individual requirement. Also we should be sufficiently conversant with surgical technique to be able to follow the operation and realize the reaction of certain procedures. We cannot always anticipate the

next step, and a word from the surgeon is invariably an aid. Our interest in the patient does not stop with the closing of the wound and the withdrawal of the anesthetic. Having watched the patient as to his condition throughout the operation, we should be able to advise as to post-operative measures, which may be necessary.

I wonder if we are always able to get the patient's viewpoint. We, working in and familiar with hospital atmosphere, may find it difficult to realize the impressions an individual may receive amid these unfamiliar surroundings, not always the most reassuring to the lay mind. Sometimes in our hurry we seem to forget the individuality of the patient and the various factors that may increase his nervous tension, and, all on edge, he is more or less hurried into unconsciousness amid strange sounds and conversation that are anything but soothing.

Do we not lose a great deal in attempts to hurry? During a crowded day, the temptation to do so is almost irresistible. Speed is a requisite in the successful carrying out of our work, and is only retarded by hurry. For instance, it does no good to hurry a patient to the operating room and then have him wait fifteen or twenty minutes before the anesthetic is begun. It does no good to hurry the anesthetic, though the combination of a refractory patient and a rushed impatient surgeon will sometimes make one try it, always to one's regret. It takes about so long to obtain surgical anesthesia, and when we try to rush it we usually find we haven't saved time, but have overdosed the patient. The use of local anesthesia by modern technique and the use of nitrous oxide, either alone or in combination, have shown us the advantages of gentle and unhurried manipulations. We have found, too, that with the more potent anesthetics that a little patience and gentleness will let us obtain the necessary relaxation without unduly saturating the patient.

In all instances proper pre-operative preparation of the patient should be insisted upon. There should be a complete physical examination and urinalysis. Too often we guess the kidneys are normal. Blood examination and blood pressure give us valuable aid in estimating the patient's condition. The advisability of using a preliminary narcotic is still perhaps somewhat of a moot subject, though most of us use one, believing that its advantages far outweigh its disadvantages.

It should be seen to that the patient is adequately protected from cold at all times, most especially during and after the operation. The position of the patient deserves more importance than it usually receives. Slight and simple adjustments can easily make it one of ease to the patient then and after, and by taking the muscles off the stretch, aid greatly in obtaining relaxation.

It should be seen to that our anesthetic apparatus is in perfect order with an adequate supply of anesthetic, and that whatever may be needful is at our finger-tips. Also that the means of stimulation or resuscitation are ready for use at all times and may be applied with the least confusion and delay.

Much in the way of preparation, examination, and various procedures for the patient's safety and com-

* Chairman's Address, Section on Anesthesiology.

fort seem most of the time to be rather small points, but if one of them is omitted at the wrong time the consequences may loom extraordinarily large.

Much benefit is to be gained by conference with the surgeon as to the progress of the case, noting the effect of the anesthetic after the operation as well as during it.

I have tried briefly to indicate various points whereby the anesthetist may co-ordinate his efforts with those of the surgeon, to the end that the patient may more certainly recover. By education, training, and a broader conception of anesthesia we become as skillful in our specialty as the surgeon is in his. Our knowledge of the subject must be that of a physician. It must be recognized that there is a close relationship between anesthesia and surgical procedure. Surgery is a therapeutic measure, done not for the sake of doing an operation, but in the interest of the patient's health. We work with the surgeon, sharing the responsibilities and co-operating with him, to the end that his success in getting the patient well may be assured. Our attempt is to render a service to both patient and surgeon in administering an anesthetic as skillfully and safely as our present knowledge and equipment will permit, co-ordinating our efforts with his toward the recovery of the patient.

2305 Sacramento Street.

More About Tryparsamide in Neurosyphilis—John H. Stokes and Louis F. X. Wilhelm (Archives of Dermatology and Syphilology, May, 1925), after an exhaustive discussion of the benefits and dangers from the use of tryparsamide in combating the most damaging enemy to human health, arrive at the following conclusions among others: 5. "Tryparsamide treatment is superior to other forms of treatment for neurosyphilis on the score of minimal expense, inconvenience and loss of time, and maximal symptomatic gain in mental cases." 6. "Eye complications constitute a definite risk, of which patient and physician should be fully aware. An examination of the eyes by a competent ophthalmologist, with special reference to visual acuity and perimetric fields, must precede the first administration of the drug, and be repeated several times, especially during the first injections of the first course, when complications seem most likely to arise." 10. "Tryparsamide produces a definite Herxheimer-like flare-up of symptoms in mental cases which must be allowed for in making plans for treatment, and may necessitate temporary custodial care of the patient with special nursing, restraint, and precautions against violence and self-injury." 11. "The social values in a given case should be considered with reference to increased sexual activity in certain patients, and with reference to the possibility of the conversion of an unobjectionable and harmless patient into an objectionable and dangerous one." 12. "Tryparsamide appears to have a beneficial effect on patients with resistant tabes, including gastric crises, even though the spinal fluid may be negative." 13. "Our results in the treatment of late paresis by tryparsamide in an institution for the insane are disappointing and do not lead us to continue it in this field. The unfavorable progress of certain unfavorable cases may apparently be hastened by the drug." 14. "We are still disposed to regard tryparsamide, because of the possibility of eye complications, as a last rather than a first therapeutic resort in asymptomatic neurosyphilis. In obvious early paresis, we recommend its use after or in conjunction with other forms of treatment. The experience of other observers has established its unfitness for use in most other aspects of syphilis, owing to its lack of spirillicidal power."

INJURIES TO THE URINARY ORGANS IN RELATION TO INDUSTRIAL ACCIDENTS

By ROBERT V. DAY, M. D., and HARRY W. MARTIN, M. D.,
Los Angeles

A resume of the diagnosis and treatment of injuries to the urinary organs in relation to industry.

Fractured pelvis and ruptured urethra, direct bladder injury, trauma to the spinal cord with secondary bladder involvement, direct injury to the kidneys, and epididymitis, constitute the greatest number of cases for which claims are filed for compensation.

Fractures of one or more vertebrae or injuries to the cord without fracture sometimes produce the so-called spinal cord bladder.

Kidney stone following injuries of the spinal cord is not an uncommon sequel.

The important and essential findings in severe injuries of the kidney are pain in the loin, extending through to the abdomen, fullness, dullness and tenderness in the kidney area, and hematuria.

The most numerous class of patients referred to the urologist for examination and report, on which may be based the question of compensability, are those with epididymitis.

If there is no existing source of bacteria, even though there is an injury to the testicle or epididymis, inflammatory reaction will not result.

DISCUSSION by Granville MacGowan, Los Angeles; Charles P. Mathe, San Francisco; Miley B. Wesson, San Francisco.

TRAUMATIC injuries involving the urogenital organs, as seen in Southern California, have increased apparently several hundred per cent in the past ten years. The development of new industries, particularly shipbuilding and oil production, and the enormous increase in population, together with the popularity of the automobile, are the principal factors causing the increase. Fractured pelvis and ruptured urethra, direct bladder injury, trauma to the spinal cord with secondary bladder involvement, direct injury to the kidneys, and epididymitis constitute the greatest number of cases for which claims are filed for compensation.

If the bulb and membranous urethra are injured, it is usually the result of falling astride some hard, firm object or in connection with fractured pelvis. As a rule, the prostate urethra escapes serious injury, and injury to the pendulous urethra is also rare. When the urethra is injured the symptoms are pain, bleeding, disturbance of urination and tenderness, with tumefaction. The location of the tumefaction, the point of obstruction to the catheter, and the consideration of the mechanical circumstances and causative force attending the accident will usually determine the point of injury and, in a rough way, its extent. The tumefaction is primarily due to extravasation of blood, to effusions, and secondarily to extravasation of urine and inflammatory exudate. Extravasation follows the fascial planes, usually discoverable in the perineum; also the scrotum and penis, and may involve the rectovesical space toward the peritoneum if the prostate urethra is much torn. Altogether, the extent of the extravasation is problematical. It may ascend to the diaphragm retroperitoneally, as in one case observed at a coroner's necropsy. In this case the rectum and peritoneum were torn somewhat. With injuries of the ilium and sacro-iliac joint, immense retroperitoneal hematomas over the psoas muscle may develop. (We saw this once in a case that recovered perfectly, where

the peritoneum was opened and examined by an abdominal surgeon just previous to our taking up the urological procedure as soon as he had closed the peritoneum.) The wide extravasation causes shock, and the extravasated blood and hematomas are apt to become infected. The extravasation sometimes extends down the inside of the thigh, requiring subsequent drainage. Knowing the extent of the injuries, the authors believe, if the patient is not greatly shocked, that the best procedure is to immediately open the bladder suprapubically, pass a retrograde staff through the bladder out to the perineum, and buttonhole the perineum down to the staff; a rubber perineal tube is then slipped over the end of the staff, which, when withdrawn into the bladder, carries the rubber perineal tube with it. When the tube is well in the bladder it is slipped off the staff and fixed with a skin suture in the perineal incision. The suprapubic bladder opening is finally sutured water-tight around a Pezzer catheter, with rubber tissue drainage in the prevesical space. This prevents further urinary infiltration, allows the extravasated blood and urine, plus the infiltrating exudate of cells and serum, to leak out, and thus prevents its final organization into thick dense scar tissue, which would otherwise result in a bad traumatic stricture if the patient in the meantime did not succumb from infiltration and sepsis. The classical procedure, of course, is to perform perineal section, insert a catheter into the bladder and suture the urethra if possible. We do not do this, as a rule, and especially in case of fractured pelvis, for the following reasons: First, it requires the exaggerated lithotomy position which, if the pelvis is fractured, might drive spicules of the fractured pelvic bones farther into the tissues; second, it consumes considerably more time; third, the edges of the urethra are usually so torn and contused that the sutures almost never hold. When the exudate has disappeared and the tissues lose their friability, a secondary suture may be attempted; but it is seldom necessary, since the great cause of the scar constituting traumatic stricture is the organization of the cellular exudate in the presence of infection into fibroblasts and adult scar tissue.

When the suprapubic incision is made, marked bloody extravasation in the loose prevesical and perivesical cellular tissue is usually found. Direct injuries to the bladder, particularly if the bladder is full, may in rare instances result in rupture—occasionally so small as not to be recognized, but allowing extravasation of blood and a little urine. In these latter cases, insertion of a rubber tissue drain into the prevesical space and the use of a retention catheter will usually suffice. Cystoscopy is justified only when the symptoms point to rupture of the bladder with little or no urethral injury and no fracture of the pelvis.

Prostatism: Occasionally, a man of prostatic age sustains a slight injury to some region of the body and suddenly develops difficulty in urinating, hematuria, perhaps epididymitis, or acute retention. He stoutly maintains that he has never had any previous urinary troubles and that the injury is entirely responsible for his condition. What really happens is that the psychic shock has so diverted his atten-

tion or so benumbed him that he neglected to urinate at the proper time; then his bladder became distended and he was unable to urinate. (As a matter of fact, most prostatitics have their condition brought home to them acutely by neglecting to urinate at the proper time, and the distention causes prostatic engorgement, pain, and reflex spasm of the cutoff muscle, resulting in partial or complete retention. If the urine is infected, epididymitis may result.)

Fractures of one or more vertebrae or injuries to the cord without fracture, sometimes produce the so-called spinal cord bladder with residual urine, paradoxical incontinence, infection, and the typical cystoscopic picture. These cases really belong to the neurologist and neuro-surgeon. Their urinary symptoms will improve exactly in proportion to the regeneration of the nerve tissues involved.

It has been noted repeatedly by men doing much industrial compensation work that kidney stone following injuries of the spinal cord is not an uncommon sequel. This is not surprising, since residual urine and stasis, with resulting infection, predispose to both ascending and hematogenous infection.

Few men have had large experience with fractured or ruptured kidneys. Keyes, in the 1923 edition of his text-book, states that he has operated on four cases. Connell, in 1916, was able to gather only 841 cases, in a review of the literature. Tuffier and others have collected a series of cases—not their own—but these were of wartime injuries to combatants and, of course, are not quite comparable to industrial accident cases. The literature on the subject is somewhat meager. One of us (Day) has performed nephrectomy on four cases, with no deaths. In addition to these four, we have seen six other cases in which there was no doubt of injury to the kidney, but which recovered under expectant treatment. Still another two cases were seen at operation several years after the injury. The important and essential findings in severe injuries of the kidney are pain in the loin, extending through to the abdomen, fullness, dullness and tenderness in the kidney area, and hematuria. Hematuria often ceases in a few hours, even if the injury is considerable, due to the clotting of the escaped blood in the perirenal space, as well as blocking of the ureter by clots.

The amount of shock depends on many factors: First, associated injuries, particularly to the other abdominal viscera, diaphragm and lower chest; second, extent of injury; third, loss of blood; fourth, temperament, age, general health and associated chronic diseases of any other important organ.

It is amazing to observe how comparatively little shock is associated with the most extensive fracture of the kidney, provided the case is otherwise uncomplicated. For example, in two of our cases, in which the kidney was completely bisected about midway between the poles and in which nephrectomy was done in each instance about forty-eight hours after the injury, there was surprisingly little shock at any time preceding or after the nephrectomy. The injury may result in a rupture of the main renal vessels or the kidney may be shattered to a pulp. In case of complete rupture the blood

and urine escaping may be confined to the perirenal space. Again, it may rupture through the perirenal fascia and extend as an extravasation retroperitoneally, even down to the true pelvis. This happened in one of our cases and clinically resulted in a psoas abscess requiring secondary operation for drainage two weeks following nephrectomy. The rupture may be slight and result in only a subcapsular hematoma, which later becomes cystic. Many years ago one of us (Day) assisted the late Dr. N. H. Morrison in such a case. There had been little injury to the kidney itself, but we found a subcapsular cyst the size of a small lemon. On the other hand, the kidney may be entirely destroyed and converted into a cystic tumor—pseudo-hydronephrosis, and may later become calcified. For example, a boy 18 years of age sustaining injury to the back seven years previously, had aspiration of a cyst in his loin three times during the year following the injury; six years later he applied for compensation, claiming an injury to his back. X-ray revealed a calcified cyst in the region of the left kidney, the size and shape of the head of a new-born babe. Urological findings were negative, except that the ureter on this side could not be catheterized beyond 15 cm., and no urine or cyst fluid could be obtained through the catheter. The mass was excised piecemeal and with great difficulty, and consisted of a calcified fibrous wall containing clear fluid. All kidney tissue had disappeared. Some cases which, from the clinical aspect do not appear extensive at the time of the accident, may result insidiously in serious or complete destruction of the kidney. MacGowan cites a case in which he performed nephrectomy thirteen weeks after injury for a large mass in the flank with pronounced sepsis. In one case seen by the authors nine weeks after injury, nephrectomy was performed a few days later. At the first visit his temperature was 102.4, pulse 148, hemoglobin 40 per cent, and there was great bladder tenesmus. Cystoscopy was attempted, but the great mass of blood-clots in the bladder, both old and new, entirely interfered with vision. An attempt at evacuation of clots failed, partially because many were quite adherent to the bladder wall. It was necessary to do a suprapubic cystotomy and evacuate more than a pint of clots. The patient nearly died from shock. We hoped the hemorrhage would not recur, and decided that removal of the ruptured kidney would be a highly dangerous procedure at that time. However, he had another hemorrhage two days later. Evacuation of the clots through the former suprapubic incision was done. We still hoped. Two days later he had still another hemorrhage, and after a transfusion his hemoglobin was only 35 per cent. A nephrectomy was then done, followed that night by another transfusion. Convalescence was rapid and uncomplicated. This kidney had sustained a rupture extending from the pelvis into the perirenal space. The perirenal fat was cicatricial and the kidney itself markedly fibrotic. It was necessary to do an intracapsular nephrectomy. The patient rapidly took on weight and the rise in his hemoglobin was rapid.

Another patient seen recently was injured in the oil fields February 4, 1924. Shock was not pronounced and his pulse was under 100. Frank hema-

turia for the first eighteen hours. After that only microscopic blood. During the second night his pulse was feeble and intermittent, but never over 110. Operation following morning. After the kidney was delivered, a hole large enough for one to insert a thumb through the lower pole into its pelvis was seen. Much free bleeding when and after the lumbar fascia was incised, and much free oozing from kidney-bed as kidney was being delivered. Profuse bleeding from the rent in the kidney. Therefore, nephrectomy was decided upon. Uneventful convalescence except for the advent of diarrhea from fifth to tenth day post-operatively. He had 79 per cent hemoglobin the first day after the injury, with 50 per cent the morning following operation without loss of blood from the pedicle during the nephrectomy.

If the kidney is not too severely damaged, conservative surgery should be practiced; that is, incision, gauze packing, and drainage. Sometimes when the pressure is relieved by opening up the perirenal space, hemorrhage may be serious. It is up to the surgeon at the time of operation in this class of case to determine whether or not it is safe to leave the bleeding kidney in. In Watson's series, 27 per cent of simple ruptures resulted fatally with expectant treatment. Nephrectomy resulted in 22.5 per cent mortality in 132 collected cases of simple rupture. Conservative operative treatment—gauze packing, drainage or suture—gave a mortality of 8.5 per cent in 107 cases.

Unless loss of blood or some other reason demands immediate operation, the authors believe that it is wise to wait at least forty-eight hours before nephrectomy for the following reasons: First, it allows the opposite kidney to compensate; second, there is usually a superficial necrosis of the fractured surface so that bleeding will not be alarming while delivering the kidney; third, it gives time for associated injuries of other organs to produce symptoms indicating such complications; and fourth, by waiting the operation may sometimes be avoided.

The most numerous class of patients referred to the urologist for examination and report, on which may be based the question of compensability, are those with epididymitis. They usually have pus in their prostate and seminal vesicle juice obtained by massage; whether this preceded or was caused by the infected epididymis is not always easy to determine. Others have morning drop or cloudy first glass, often containing gonococci. Most have undoubtedly latent or active infection of the prostate, seminal vesicles or urethra, or any combination of these. Others have, in addition, infected urine from other causes, as in case of pyelonephritis associated or not with stone or tuberculosis or, as in the case cited above, hypertrophied prostate. The latter was riding in an interurban bus which suddenly swerved into a shallow ditch, injuring no one, but shaking up the passengers a bit and giving them a scare. This happened just out of San Diego. The old gentleman had been getting up at night to urinate for several years, and he had been in the habit of urinating frequently in the daytime. No doubt he was considerably dulled by reason of the excitement, and he didn't attempt to urinate again until he got to River-

side, sixty miles farther on, at which time he had difficulty. He came on to Los Angeles, developed more dysuria, then epididymitis, after which he was referred by the State Compensation Insurance Fund for examination. He was 70 years old, had a greatly hypertrophied prostate, his urine full of pus, and had a residual of six ounces. He had not been physically injured at all in the accident. It appears to us that in practically every suddenly occurring case of epididymitis in industrial accidents there is a latent or active infection in the urinary tract or its adnexa, or more rarely a focus of infection elsewhere in the body from which pyogenic organisms are carried through the blood stream to the more or less susceptible epididymis. In other words, if there is no existing source of bacteria, even though there is an injury to the testicle or epididymis, inflammatory reaction will not result.

412 West Sixth Street.

DISCUSSION

GRANVILLE MACGOWAN, M. D. (Brack Shop Building, Los Angeles)—I have given careful consideration to the opinion and advice of Doctor Day, with relation to traumatic injuries to the organs concerned in urination as set forth in this article. It is not usual that those who have to look after industrial accidents have sufficient experience with the surgery of the urinary organs to decide, without embarrassment, upon the best method of procedure in cases of grave injury. To avoid prolonged invalidism, sometimes lifelong, often to save life, for the injured person, and always to save the money of the employer or the insurance carrier, an intelligent decision as to what to do should be quite promptly made. This article of Day's, let us hope, may serve as a guide to those of less experience.

CHARLES P. MATHE, M. D. (Phelan Building, San Francisco)—Doctors Day and Martin have given us a very good resume of the treatment of injuries to the urinary organs sustained in the industries. They have pointed out the importance of conservatism in the treatment of renal injuries, such conservatism often saving the kidney by avoiding nephrectomy. Recently, in a spontaneous ruptured hydronephrosis due to complete block at the ureteropelvic junction by a wedge-shaped stone with tumefaction of the affected side, severe jaundice was noted. The urine was contained within Gerota's fatty capsule, and had caused tumefaction, pressing on the gall-duct. Following operation, by which about 120 cc. of urine was liberated from the fatty tissue surrounding the kidney and the stone removed by pyelotomy, the jaundice entirely cleared up. This is significant because one might confuse this symptom for gall-bladder disease.

Acute symptoms in persons affected by prostatism and movable kidney developing after accidents often occur. The average layman is prone to blame his affliction to an accident. How frequently does one woman attribute a breast cancer to an injury, and another a tubercular knee to the trauma of a fall. I have seen acute retention develop in prostates due to congestion of the gland following excesses in alcohol or voluntary retention of urine over a long period of time.

The question of the influence of trauma on the production of movable kidney was not discussed. It would be interesting to have the opinion of the authors on this diversified subject. J. J. Bell of England, who has had a large industrial practice in a manufacturing town, states that he has observed three hundred movable kidneys develop in girls whom he claims were employed too early in life, stood for long hours, and bore heavy weights. The girls having a congenital shallow, funnel-shape renal niche, however, were the ones usually developing the nephroptosis. Harris, on the other hand, doubts the sudden or acute origin of movable kidney, and states in order that a normally fixed kidney be injured, crushed or displaced, it is accompanied by a laceration of the perirenal tissue. He does not voice his opinion on repeated trauma or strain.

The authors have pointed out that, in order to have epididymitis resulting from a trauma, there must be a pre-existing source of infection. I have seen normal uninfected athletes repeatedly injured in the testis by a fast-moving hard rubber handball, causing tremendous pain at the time of injury, fail to develop acute epididymitis. On the other hand, an epididymis previously infected, subjected to the slightest trauma, often develops inflammation.

MILEY B. WESSON, M. D. (Flood Building, San Francisco)—This paper is an excellent and timely one, and is most instructive to the surgeon who sees an occasional industrial case. Two points are brought out that are vital ones to the insurance carriers, one being the question of responsibility for traumatic epididymitis and the other the treatment of closed traumatism of the kidney.

Any person with a prostatitis or seminal vesiculitis has a potential epididymitis, which may flare up after any sudden exertion, be it jumping on a street-car, falling off a scaffold, lifting a heavy weight, or receiving a direct blow on the testicle; whereas the same injury in the ab-

sence of an infected seminal vesicle will not affect the epididymis. In other words, it is very doubtful if epididymitis should ever be considered an industrial injury.

The treatment of rupture of the kidney has not yet been standardized, and unfortunately those organs are being handled today as were ovaries a generation ago, when it was a fad to remove them for trivial reasons. Insurance carriers want, when possible, their risks put back to work with both kidneys. Of all the internal catastrophies a ruptured kidney treated under modern conditions offers the best prospect of a complete recovery. In those unfortunates with a single kidney a severe injury to that organ is probably always fatal. The indications for exploration are (a) immediate severe renal hemorrhage which endangers the patient's life; (b) steady hourly rise in pulse rate; and (c) continuous moderate hemorrhage over many days, with consequent anemia. Conservative surgery consisting of gauze packing and drainage may be sufficient. The recognized indications for nephrectomy are (1) tearing of the renal pedicle; (2) laceration of the kidney in several places; (3) a tear extending toward the renal pelvis in a kidney whose short pedicle prevents delivering it so as to expose the rent for suturing; (4) an extensive tear in the renal pelvis which cannot be repaired or a complete tear across the ureter; and (5) hydronephrosis or other severe disease of the injured kidney.

Aside from severe hemorrhage there is no other justification for operation except infection. Since hematomata are easily infected, faithful supervision of the case is absolutely necessary if conservatism is attempted.

I have recently seen five cases of acute traumatic rupture of the kidney, all of which recovered under expectant treatment and were promptly returned to full duty, with sterile urine. One case had hematuria for thirty-three days, and the bleeding was stopped by injecting by gravity with a twenty-four-inch column of 13½ per cent sodium iodide solution to make the accompanying pyelogram. At that time the function of the damaged side was 50 per cent normal (total phthalein now normal). A sixth case was first seen six months after injury, and the pyelogram showed the scar of a complete perpendicular tear that had destroyed the middle calyx. This kidney was saved, although all rules of procedure were violated; the patient fell three feet and had hematuria; for twenty-two days he was treated for pneumonia because of the leucocytosis and fever, then was operated upon by a general surgeon because of a tumor mass in the left lumbar region the size of a "small watermelon," and a "gallon of urine" was evacuated; cystoscopy seven days later showed that all of the urine from the affected kidney was being discharged through the drainage tube, and the opposite kidney was infected. This man is back at work with two kidneys, both uninfected, and the damaged one has a function of 50 per cent normal.

Doctors Day and Martin have clearly shown that the mortality of traumatic rupture of the kidney has been reduced to a vanishing point by: (1) Operative intervention for the arrest of hemorrhage which otherwise rapidly proves fatal; (2) an appreciation of those signs which heralded the failure of expectant treatment; and (3) the prevention of infection.

USE OF SODIUM THIOSULPHATE IN METALLIC POISONINGS *

By GEORGE F. ROBERTS, M. D., Salt Lake City, Utah, AND
ANDREW J. HOSMER, M. D., Midvale, Utah

Sodium thiosulphate is the logical drug of choice in the treatment of acute and chronic poisonings by a group of the heavy metals.

It materially shortens the length of disability caused by these poisons.

Moist applications of a 1 to 2 per cent solution of sodium thiosulphate are beneficial in the treatment of burns and dermatitis caused by arsenic and mercury.

DISCUSSION by Gayle Mosely, Los Angeles; C. O. Sappington, Oakland.

FOR many years chemists have used non-metallic sulphur as a precipitant for a group of heavy metals, among which are found arsenic, mercury, lead, copper, bismuth, and zinc. Toxicologists, however, apparently overlooked this precipitant action of non-metallic sulphur, and it is of only recent date that some of the non-metallic sulphur groups have been successfully used in medicine as a precipitant for these metals when taken into the body, either as a means of attempting death as a therapeutic agent, or as the result of occupation.

The chief non-metallic sulphur derivatives are calcium sulphide, calcium sulphite, and sodium thiosulphate. Sodium thiosulphate is a white crystalline substance slightly alkaline in reaction, and readily soluble in water. It is prepared by heating sulphur with sodium carbonate, dissolving this resultant in water, filtering, boiling the filtrate with sulphur, refiltering and concentrating. It converts all of the

soluble toxic metals mentioned into insoluble non-toxic compounds.

The work on which this report is based, covering the treatment with sodium thiosulphate of acute and chronic poisonings by metals of this group, has been carried out at the Salt Lake County Hospital, St. Mark's Hospital, and the plant of the United States Smelting and Refining Company at Midvale, Utah.

The first cases we will report are those of two typical ones of arsphenamin dermatitis.

Case No. 1—Mr. J. H., American, age 53. Gave a four plus Wassermann test. He had a chronic syphilitic osteomyelitis, which had been operated upon several times, with a resultant suppurating fistulae. He was given .400 of salvarsan. In five days this dose was repeated. The day following this dose he developed a macular rash upon the face and hands. The next day the entire body was red. His hands, legs, and face were swollen. There was a serous exudate involving principally his face and arms. He was immediately given sodium thiosulphate .500 intravenously in 20 cc. of water. The following day he was given .900. With the second dose his symptoms began to disappear. By the time he had received five doses his symptoms were gone, and by the twelfth day he had completely recovered.

Case No. 2—Mr. W. W., age 52, was suffering with a syphilitic gummas of the arm and leg. Anti-syphilitic treatment was started. He received, covering a period of two months, nine doses of salvarsan. The first course consisted of six doses, and the second three. Three days following the last injection the skin of the face and neck became red, dry, and itching. Two days later the eruption spread to cover his body. The skin was red, swollen, and weeping. The first day he was given .3 gm. of sodium thiosulphate intravenously, the second day .3 gm., the third day .45 gm. By this time the edema had practically disappeared and the redness was diminishing. He was given subsequent doses of .6, .9, 1.2, and 1.8 gms. By the fifteenth day his symptoms had all disappeared and his skin was normal.

These cases illustrate the effectiveness of this preparation in shortening an attack of arsphenamin dermatitis from two months or longer to as many weeks.

The success which we have had in the treatment of local dermatitis and burns due to the external application of arsenic have been equally as gratifying, as has that of treating arsphenamin dermatitis. These cases are too numerous to tabulate, and one case will probably suffice for the entire group, as all have reacted practically the same.

Case No. 3—Mr. C. P. O., American, age 37, employed in the bag-house at the smelting plant. He complained of stiffness of arms, legs, fingers, and toes. The exposed surfaces of his body were very red. There were several ulcers on his hands. Lotions had been applied to the skin, and ointments and boric acid dressings to the ulcers. Very little progress was noted. The skin continued to itch and burn, and the ulcers refused to heal. He was given six doses of sodium thiosulphate intravenously, ranging from .3 gm. on the first day to 1.8 gms. on the sixth day. By the sixth day the redness of the skin had diminished, and by the eighth day the itching had all disappeared. The stiffness and soreness of the muscles had completely gone. The ulcers on the hand had been treated additionally by moist applications of sodium thiosulphate and a solution of the drug had been given by mouth. The ulcers rapidly cleared and by the end of the second week had completely healed.

Previous to the use by us of sodium thiosulphate, the men who worked in the bag-houses and arsenic plants were required to take a shower and a complete change of clothing when coming off shift. Despite these precautions, there were numerous arsenic

*Read before the Salt Lake County Medical Society.

burns and arsenic dermatitis. Noting the very favorable effect of solutions of sodium thiosulphate externally, we recommended that the employes in the bag-house and arsenic plants be required to take a daily shower in a solution of sodium thiosulphate. The men are now required, when coming off shift, to take a shower bath from a tank containing a 1 per cent solution of sodium thiosulphate. After this they then take their cleansing bath and change of clothing. They are also given an ointment of 1 gm. sodium thiosulphate to the ounce. This is put in the nostrils, around the eyes, and in the ears. Since the introduction of these precautions, arsenic burns, dermatitis and irritations of the nose and eyes, and abdominal colics, have become the exception rather than the rule; the men are happier, do better work, and little complaint is heard concerning their occupation.

Our experience with acute and chronic lead poisoning has been more phenomenal than has been that of arsenic; in fact, it has now become the routine that all men applying for treatment and complaining chiefly of vague abdominal pains, even before the blood shows any change, are immediately given intravenous doses of sodium thiosulphate, with the result that, after two to three doses, they are completely free from pain. As with arsenic, so with lead, these cases have been too numerous to give a complete tabulation here, but two cases, one from the smelter and one from a city plumber, will probably suffice as typical group pictures.

Case No. 4—Mr. J. S., Serbian, age 40, had been away from duty for one week on account of abdominal pain. His family physician had used all of the better known remedies for lead poisoning, with practically no effect. At the beginning of the second week he applied to us for treatment. The first day he was given 1.2, 1.6 and 1.8 gms. of sodium thiosulphate intravenously. The second day the dosage was repeated. By the third day his pain had all disappeared. The third day he was given two doses of 1.6 and 1.8 gms. each. The fifth day he returned to work a well man, and has not applied for any treatment since that time.

Case No. 5—R. J., negro, plumber, age 32. For two months he had been practically incapacitated on account of abdominal pain. One month of this time had been spent in hospitals. On admission to the county hospital, he was in such pain that his thighs were almost completely flexed on his abdomen. His bowels had not moved for four days. He was given $\frac{1}{2}$ grain morphine, 2 ounces of magnesium sulphate, and three doses of 1.6 gms. each of sodium thiosulphate the first twenty-four hours. The next day his pain was greatly relieved. The sodium thiosulphate was again repeated. The second day his pain had practically disappeared. The third, fourth, and fifth days he was given two doses each day of 1.2 gms. By the sixth day his pain had all gone, and he left the hospital to return to his work.

Our experience with mercurial poisonings has not been as extensive as it has been with arsenic and lead, but we believe that the results have been sufficient to warrant the recommendation that this chemical be kept on hand in all emergency hospitals where a dose could be immediately given in any case of mercurial poisoning.

Case No. 6—Mrs. J., American, age 23, took by mouth thirty 1-grain tablets of bichloride of mercury. She was found about four hours later. She stated that she had vomited about one hour after taking the tablets. She was taken to the Emergency Hospital, where she was given a stomach lavage, and later was brought to the County Hospital. At this time she was passing blood from the

bowels and vomiting blood and bile. The urine was scanty and smoky. The abdomen was distended and tender, especially over the ileocecal region. By March 1 the tongue was so swollen that it practically filled the mouth. The teeth were loose and there was marked necrosis of the gums. March 7 she aborted a six weeks' partially macerated foetus. March 8, patient in partial coma. Refused all food or liquid by mouth. March 10, .3 gm. sodium thiosulphate was given intravenously. March 11, 45 gms. March 12, 6 gms. March 13, 9 gms. March 15, 1 gm. March 17, 1.2 gms. March 19, 1.8 gms. By March 11, the day following the first dose, the patient was some brighter, the tongue not as badly swollen, and she asked for food. March 15, appetite good. Tongue decreasing in size. Teeth very loose, but necrosis of gums is improving. March 20, tongue practically normal. Gums greatly improved. Loose teeth and some necrotic bone removed. April 1, sent to the county jail. The mouth is a little tender, but otherwise she is practically normal.

Case No. 7—J. B., American, age 24, took two tablets of bichloride of mercury, $7\frac{1}{2}$ grain, in mistake for other medicine. He discovered his mistake in about one hour. A stomach lavage was immediately given and an intravenous dose of 1.6 gms. of sodium thiosulphate. This dose was repeated in four hours. The following day the urine gave a test for mercury. He was given eight doses averaging about 1.5 gms. of sodium thiosulphate. He made an uneventful recovery with no symptoms of mercurial poisoning, except a looseness of the bowels and some tenesmus.

Case No. 8—R. H., age 28, took 100 1-grain tablets of bichloride of mercury. He was found about one and one-half hours later. At this time he was vomiting blood, and passing blood from the bowels. He was sent to a hospital, where he was given sodium thiosulphate both by mouth and intravenously. The hemorrhage from the bowels, bladder and stomach continued, and he died twelve hours later.

Case No. 9—D. H., age 45, had scabies. He put one heaping tablespoonful of powdered bichloride of mercury in a pint of water and rubbed it on his body. When seen by us four days later he had a complete suppression of urine which had been present for two days; practically the entire surface of his body was burned. He was given sodium thiosulphate, 1 gm. intravenously every eight hours, and was given 15 gms. the first day by mouth and afterward 5 gms. daily. Moist applications of a 2 per cent solution were applied to the burned surfaces. The first two days after treatment was started he continued to pass blood from the bowels. This disappeared, but the bowels remained very loose. The burned areas greatly improved, but he died on the ninth day, having then had a complete suppression of urine for seven days.

Some of the earliest work on the use of sodium thiosulphate in metallic poisonings done by McBride and Dennie, they advocated the following dosage: .3 gm. first day; .45 gm. second day; .6 gm. third day; .9 gm. fourth day; 1.2 gm. sixth day, and 1.8 gm. the eighth day. We have found that these dosages can be greatly increased with a resultant more rapid modification of the symptoms and with no unfavorable manifestations or discomfort to the patient. In our earlier work we followed the dosage of McBride and Dennie, but in our later work we have been using, as an original dose, 1 to 1.2 gms. and as high as 1.8 gms., and have repeated this dose from two to three times daily. In all cases treated we gave sodium thiosulphate by mouth daily. The first day the patients were given 15 gms. in 500 cc. of water, and daily thereafter 5 gms. in the same amount of water, distributed as small drinks throughout the day.

CONCLUSIONS

1. Sodium thiosulphate is the logical drug of choice in the treatment of acute and chronic poisonings by group of heavy metals.

2. It materially shortens the length of disability caused by these poisons.

3. Its more general use by corporations where the health of employes is influenced by these metals should be urged.

4. Moist applications of a 1 to 2 per cent solution of sodium thiosulphate are beneficial in the treatment of burns and dermatitis caused by arsenic and mercury.

5. In acute cases of poisonings by these metals, the original dose of sodium thiosulphate should be 1 gm. intravenously given once, twice or three times daily, depending upon the symptoms.

6. In our series of over one hundred cases we have had no reactions in either large or small doses, and the only effect we have seen between the large and small doses is a more rapid amelioration of symptoms.

DISCUSSION

GAYLE G. MOSELEY, M. D. (National City Bank Building, Los Angeles)—The paper of Drs. Roberts and Hosmer serves to emphasize the importance of scientific medicine to industry. I hope in the near future some ethical way may be found to bring to the attention of industry the developments in medicine and surgery that have a direct relation to business. This could be done through the publications of the various trade associations. Any measure that serves to lessen the period of disability of a sick or injured employe not only lessens the suffering of the employe, but means an actual saving of money for both employer and employe. If the employe receives compensation during his period of disability it is much less than would be his actual earnings.

I am particularly interested in the results obtained from the sodium thiosulphate in lead poisoning. Notwithstanding the great advance made in the prevention of this trouble, it is still seen quite frequently in industrial cases. Many of the smaller concerns, such as small plumbing and painting contractors, take no special precautions to prevent this disease. Sometimes special conditions arise in large plants that cause much sickness and suffering to the employes, as well as expense to the employer, before the necessary steps can be taken to prevent the trouble. Within the past year one of the largest shipbuilding concerns in the bay district had a contract to tear down a number of Government vessels. These boats, of course, had all been painted many times with white lead, and the result was a very large number of cases of lead poisoning, some of which were quite serious. In fact, the condition was so bad that the insurance carrier had to cancel the risk, at considerable loss. This example is cited simply to show that lead poisoning is always with us.

It seems to me that early recognition of these cases is of great importance, in order that treatment may be administered before changes take place in the blood. Doctors engaged in industrial medical practice should always be on the lookout for cases of lead poisoning, as they often occur unexpectedly and from plants where ordinarily one would not expect such cases to occur. If the readers of the Journal will bear in mind that lead poisoning is much more common than generally supposed, and make early diagnosis and apply the treatment recommended in this paper, it will be another long step forward in showing the business man that he needs the doctor in this business.

C. O. SAPPINGTON, M. D. (Hutchinson Building, Oakland)—Drs. Roberts and Hosmer have brought to our attention a very interesting chemotherapeutic reaction. The administration of calcium sulphide to workers exposed to lead is not new, and is alluded to in the literature by Sir Thomas Oliver, Marvin Shie, Alice Hamilton, and other experts on lead poisoning; but the intravenous injection of sodium thiosulphate as a rational therapeutic procedure in cases of metallic poisoning, is new and certainly seems full of promise, in the light of the experience of Roberts and Hosmer.

It appears that sodium thiosulphate would be the logical drug of choice in acute and chronic cases of poisoning from the heavy metals, with the exception of chronic plumbism. We know from the excellent researches of the Harvard Lead Unit, which recently completed three years of experimental and clinical work on various phases of lead poisoning that, in the chronic type of lead intoxication, the lead is stored in the compact portion of the long bones. Various substances were tried, in order to ascertain just what was most efficacious in releasing the stored lead. Among other factors, it was discovered that a distinct change in the acid-base equilibrium toward the acid side would release the combined lead and set it free in the circulation so that it might be eliminated (of course, this is a dangerous process and may give rise to acute symptoms). Phosphoric acid in dilute solution was found to be the substance causing the setting free and excretion of lead in greatest amounts, as checked by estimations of lead in the urine and stools. I must confess my ignorance as to the relative merits of the thiosulphate of sodium as a compound which will cause lead excretion; but if it was possible that the insoluble, non-toxic compound formed by the thiosulphate could be eliminated by way of the urinary or gastro-intestinal tracts, after lead had been set free in the circulation by the use of dilute phosphoric acid, it would appear that the procedure of Drs. Roberts and Hosmer would be a very valuable adjunct in the deleating process in cases of long-standing chronic plumbism.

Dr. Moseley has spoken about the importance of lead poisoning as a problem of industrial medicine. I should like to add just a few words to what he has said. Many cases of lead poisoning are not recognized in industry because the industrial physician has not taken the trouble to familiarize himself with the progress made in the recognition of early signs and symptoms of this affection. Lead intoxication contributes over half of all the cases of poisoning due to contact with metallic substances used in various industrial processes. Where a lead hazard is definitely known to exist, certainly all the intelligence possible should be brought to bear on the aspect of prevention.

Transfusion of Lymphocytes—A patient in an advanced stage of generalized lymphosarcoma, whose white blood cells were 6400 per cubic millimeter and lymphocytes 15.5 per cent, was transfused by G. R. Minot and Raphael Isaacs, Boston (Journal A. M. A., June 6, 1925), with 450 c.c. of blood from a patient with chronic lymphatic leukemia, whose white blood corpuscles numbered 89,000 per cubic millimeter and lymphocytes 95.6 per cent. This transfusion produced no greater benefit than one with normal blood. The transfusion caused the percentage of lymphocytes in the recipient's peripheral blood to be increased immediately about threefold, and their absolute number nearly four times. The number and percentage of lymphocytes dropped almost to their pretransfusion level within thirty-five minutes of the completion of the transfusion, and reached this level within at least two and a quarter hours without a subsequent significant change. There was no evidence that the transfused lymphocytes were destroyed in the peripheral circulation.

Tryparsamide in Treatment of Neurosyphilis—Continued observation, with a larger number of cases and over a longer period of observation, has convinced Udo J. Wile and Lester M. Wieder, Ann Arbor, Mich. (Journal A. M. A., June 6, 1925), of the value of tryparsamide in producing clinical betterment in almost 30 per cent of a carefully selected group of cases. In the main, clinical improvement was not paralleled by striking changes in the spinal fluid, many of the most strikingly improved patients retaining, after protracted treatment, the changes in the fluid that were found at the original examination. In a small group of cases in which spinal fluid change was noted, clinical betterment was found to be associated with such improvement. When improvement occurred clinically, this was indicated in a large majority of the cases during the first and second courses of treatment.

BACKACHE IN GYNECOLOGY—A STUDY OF ITS FREQUENCY AND MEANING

By FRANK W. LYNCH, M. D., *San Francisco*

(*From the Department of Obstetrics and Gynecology, University of California Medical School*)

As a result of a preoperative and follow-up study of 608 gynecologically operated cases, we believe we are justified in the following conclusions:

1. Sacral or sacrolumbar backache constituted a complaint in 48 per cent of 608 gynecologic cases, being found in 8 per cent of the ovarian tumors, 31 per cent of the fibroids, 46 per cent of pelvic inflammatory disease, 58 per cent of suspensions, 75 per cent of relaxed vaginal outlets, and 23 per cent of procidentia.

2. Backache may be ascribed to gynecologic pathology because it remained cured for periods ranging from one to eight years in 77 per cent of the 48 per cent of the 608 gynecologic cases that had this symptom.

3. Backache which was cured by gynecologic operation occurred in the following percentages of the cases that had this preoperative symptom: 100 per cent in ovarian tumors, 84.5 per cent in marked retroflexions, 81 per cent in extensive vaginal relaxations, 73 per cent in chronic pelvic inflammations, 68 per cent in fibroids, and 36 per cent in complete procidentia.

4. Backache in gynecologic conditions is due chiefly to pelvic congestion.

5. Orthopedic conditions were responsible for between 17 per cent and 23 per cent of the total number of backaches of the series.

DISCUSSION by Alfred Baker Spalding, *San Francisco*; Titian Coffey, *Los Angeles*; Walter I. Baldwin, *San Francisco*.

MODERN medicine clearly demands that anyone who attempts a study of backache should proceed with the greatest caution, because the individual with backache usually has a number of co-existent conditions, any one of which may cause the complaint. The student of backache in gynecology must keep in mind that, while the symptom may arise from a number of bone, joint, visceral or pelvic lesions, it may come equally well from muscular or mental fatigue alone and without any associated condition, or from several of them in combination. Fatigue is often urged as the most common cause of backache, and, because nearly all gynecologic cases complain of fatigue, many writers urge that backache in gynecology is due rather to fatigue than to the pelvic condition.

In older times, backache in women was ascribed usually to some pelvic disorder and little attempt was made to find any orthopedic condition. More recently the pendulum has swung the other way, and the orthopedist now is often at fault for failure to rule out pelvic pathology by a routine vaginal or rectal examination. There is considerable excuse for this, however, since many contributors to medical literature urge that backache is only rarely due to a gynecologic condition. A review of several of these articles strongly suggests that many of them present the author's *impressions* rather than deductions from a series of well-controlled observations.

From the standpoint of pure theory, it seems reasonable to believe that pelvic disorders may cause backache, since women with comparatively slight pelvic pathology frequently complain of backache only at the time of menstruation or of menstrual

congestion. There is abundant proof to show that many women complain bitterly of backache until they are relieved by the cure of their dysmenorrhea, or of a marked uterine retroflexion. Backache in these cases is confined to the sacral or lowest lumbar region and most commonly is referred to the upper sacrum. It is not likely to be confused with the backache of fatigue which is usually referred to the dorsal region, but is frequently confused with orthopedic conditions.

Our study of backache in gynecology is developed from a series of 608 cases which have been studied sociologically and medically before operation, and who have been followed accurately for a minimum of one and a maximum of eight years. The cases comprise 505 laparotomies, many of which had vaginal work in addition, and 103 cases in which vaginal repair work only was done. In calculating our results, we have considered that when the patient was permanently cured of backache by gynecologic operation we were justified in concluding that the backache was due to the pelvic pathology, although there is the chance that the good result might be due occasionally to an improved general condition. We are fully conscious of the many errors that may attend such a paper, largely because the cases were not developed years ago primarily for this investigation. We realize that our series, to be of the greatest value, should be studied in similar groups of like postural defects, of stance, etc., as long since advocated by Dickinson, or after they had been arranged in various subdivisions, according to their nervous reactions. Our cases, moreover, should have been contrasted with normal controls. While we could have arranged a series on this general plan, it would have been too small to be of much value, and for that reason we have confined our study of backache to groups of similar pelvic pathology.

Backache in the sacrum or in the lower lumbar region was a pre-operative symptom in 48 per cent of the 608 cases, and did not constitute a complaint in 52 per cent of the cases. Our follow-up suggests that it was due to a gynecologic condition in 37 per cent of the entire series, since the complaint disappeared following operation and did not again constitute a symptom during the one to eight years' follow-up period after operation. This 37 per cent of the total series constitutes 77 per cent of the cases complaining of backache. There are, in addition, 17 per cent of the cases having backache whose backache was not cured by the operation, and another 6 per cent whose backache was only improved after operation. We believe these figures indicate that orthopedic conditions may have been responsible for at least 17 per cent of all the sacral lumbar backache in this series, and possibly for part of the 6 per cent of cases whose backache was only improved following operation. At any rate, the backache was diagnosed as orthopedic prior to operation in a very considerable number of cases in the series, all of which were included in this review which attempts a study of the frequency and meaning of backache in gynecology.

Our 608 cases consisted of 12 ovarian tumors, 60 fibroids, each tumor being of more than 8 cm. diam-

eter, 267 pelvic inflammatory diseases, 166 marked retroflexions, 56 generally relaxed vaginal outlets, including cervical lacerations and infections, and 47 cases of complete prolapse. The cases were first studied in the above divisions. In order to study the influence of injury and defects of the pelvic floor as a cause of backache, the various groupings were further subdivided as (1) the pathology was entirely intra-abdominal, or (2) presented only cervical pathology in addition, or (3) combined vaginal relaxations and cervical pathology, with intra-abdominal conditions, or (4) was confined entirely to cervical lacerations and infections, together with vaginal relaxations.

The pelvic inflammatory cases consisted entirely of chronic cases. They were studied in two general groups, accordingly as they were mild or more severe cases. The former consisted of 134 cases, in which at operation it was necessary to remove only one tube and ovary, or rarely both tubes and one ovary, with or without vaginal work in addition. Nearly all of this group presented posterior displacements of the uterus which were brought about by the inflammatory process. Such cases must be carefully distinguished from the non-inflammatory type of displacement, to which they bear no resemblance. The more severe type of pelvic inflammatories were represented by 133 cases, in which it was necessary to perform a hysterectomy. These were studied in groups of supravaginal (83), and panhysterectomies (50), subdivided again according to the treatment of the adnexal disease and vaginal floor.

Low backache was present in but 8 per cent of the ovarian tumors, in 31 per cent of the fibroids, in 46 per cent of the pelvic inflammatory cases, in 58 per cent of the retroflexions, in 75 per cent of the marked vaginal relaxations in women in the menstrual age, and in only 23 per cent of the complete prolapse cases. Taking the series as a whole, backache was cured by operation in 8 per cent of ovarian tumors, in 22 per cent of fibroids, in 33 per cent of pelvic inflammatories, in 50 per cent of retroversions, in 60 per cent of vaginal relaxations, but in only 8 per cent of the complete prolapse cases. Of the cases in which backache was a pre-operative symptom, the complaint was cured by the gynecologic operation in 100 per cent of the ovarian tumors, in 84.5 per cent of the retroflexions, in 81 per cent of the relaxed vaginal outlets, in 73 per cent of the pelvic inflammatories, in 68 per cent of the fibroids, and in only 36 per cent of the procidentias.

Detailed study of our cases shows that sacral-lumbar backache in gynecology follows closely upon chronic disturbances of the pelvic circulation. Thus, low backache is uncommon with uncomplicated medium size (more than 8 cm. diameter) ovarian tumors and fibroids unless there are degenerations, or incarcerations, or the fibroid is a submucous growth with hemorrhage as a prominent symptom. Backache is often absent even when the circulation is developing rapidly in quickly growing but otherwise uncomplicated tumors because there is, we believe, no chronic passive pelvic congestion. Backache often disappears when a rapidly growing uncomplicated tumor rises from the pelvis into the

abdomen, reminding us of the similar finding in the third and fourth month of pregnancy.

Added support is given to the above theory by study of the retroversions and retroflexions. By simple retroflexion we mean the retroflexions not complicated by pelvic inflammatory disease or by cervical or vaginal lacerations or infections; that is to say, the cases in which the grossly apparent pathology is limited entirely to the retroflexion. We are perfectly aware that there is not complete agreement that the so-called simple retroflexions and retroversions cause symptoms. We have, however, elsewhere *proved* by a follow-up study of a considerable number of cases that retroflexed uteri of the third degree cause definite symptoms when the uterus is enlarged, and the displacement has followed parametrial injuries during parturition; also, that the following conditions are factors in the development of symptoms: enlargement of the uterus because of chronic passive congestion, varicose veins in the broad ligaments, and the prolapse of enlarged ovaries into the pelvis. We do not believe that retroflexions of other types are a cause of symptoms.

An entirely different type of retroversio-flexions is found in pelvic inflammatory cases. In this group, the retrodisplacement is secondary and represents nature's effort to wall off a pelvic infection. The uterus is not usually enlarged, since the chief lesion is in the tubes or ovaries. Backache is not a frequent complaint in the latest stages of these infections, since the pelvic circulation has been cut down after the infection has become limited. Our study shows that backache was frequent in chronic pelvic inflammatory cases when the uterus was enlarged and congested, and there was frequent or severe bleeding. It is worthy of emphasis that backache was present in 58 per cent of the simple retroversions and in only 46 per cent of retrodisplacements associated with tubo-ovarian inflammation. The backache was cured by gynecologic operation in 85 per cent of the uncomplicated retroflexions, in 87 per cent of the mild inflammatories associated with adherent enlarged uteri in retroflexion or retroversion, and in only 64 per cent of the latest stages of the more extensive types of pelvic inflammations.

The influence of pelvic circulatory disturbance in causing backache is shown in another phase of retroflexion. A retroflexion which for years has caused symptoms will become symptomless after the menopause has cut down the pelvic circulation.

A review of the relaxed vaginal outlet and endocervicitis cases gave interesting findings. Backache was present in 75 per cent of women under 40 years who presented only this type of pelvic pathology. It was cured by gynecologic operation in 81 per cent of the cases. Study of our tables also shows that the percentage of backache is increased in any group of intra-abdominal pelvic pathology if the cases have vaginal relaxations in addition. In marked contrast to the findings in relaxed vaginal outlets are those in prolapsus, which is, of course, the last degree of vaginal relaxation. Backache in complete prolapse was present in only 23 per cent of the cases, and was cured by operation in but 36 per cent of them. This is opposed to a frequency of backache in 75 per

cent of the vaginal relaxations in the comparatively young, of which 81 per cent were cured by operation.

The marked difference in the percentage of backache in relaxed vaginal outlet cases and in those of prolapse can be explained only on the basis of circulatory restrictions and loss of function in the procidentia cases. Many of the prolapse cases stated that they had backache when they were younger and before the uterus "came down." The large number of backaches in procidentia remaining uncured by operation calls attention to the fact that these women usually have markedly relaxed or pendulous fat abdominal walls, with bad posture and other static conditions.

As a result of a pre-operative and follow-up study of 608 gynecologically operated cases, we believe we are justified in the following conclusions:

1. Sacral or sacrolumbar backache constituted a complaint in 48 per cent of 608 gynecologic cases, being found in 8 per cent of the ovarian tumors, 31 per cent of the fibroids, 46 per cent of pelvic inflammatory disease, 58 per cent of suspensions, 75 per cent of relaxed vaginal outlets, and 23 per cent of procidentia.

2. Backache may be ascribed to gynecologic pathology because it remained cured for periods ranging from one to eight years in 77 per cent of the 48 per cent of the 608 gynecologic cases that had this symptom.

3. Backache which was cured by gynecologic operation occurred in the following percentages of the cases that had this pre-operative symptom: One hundred per cent in ovarian tumors, 84.5 per cent in marked retroflexions; 81 per cent in extensive vaginal relaxations; 73 per cent in chronic pelvic inflammations; 68 per cent in fibroids; and 36 per cent in complete procidentia.

4. Backache in gynecologic conditions is due chiefly to pelvic congestion.

5. Orthopedic conditions were responsible for between 17 per cent and 23 per cent of the total number of backaches of the series.

University of California Hospital, San Francisco.

DISCUSSION

ALFRED BAKER SPALDING, M. D. (Stanford University Hospital, San Francisco)—Doctor Lynch should be congratulated for his statistical study of sacral backache in women. No doubt to many gynecologists it will be interesting to learn that with a large group of clinic patients suffering from marked pelvic lesions, 52 per cent failed to mention sacral backache as one of their symptoms. From my clinic and private experience in gynecology, I had come to the erroneous opinion that practically all women in the child-bearing period have sacral backache.

Keiffer in 1900 described special cells found in the uterus of women which resemble ganglion cells of the sympathetic type, a majority of which are on the surface of, or near the uterine blood vessels of all sizes. Though existing throughout the mucosa they are especially found along the vessels and under the epithelium of the glands. Keiffer states that the uterine ganglia undergo certain changes as do those of the cerebrospinal system in general as a result of pathological changes within the uterus such as growths, suppurative conditions or inflammation.

The sacral plexus separated from the pelvic viscera only by the pelvic fascia readily receives its share of general pelvic infection. It is well to remember that after operation, these nerve changes being chronic, demand

many months of rest before returning to the normal. After the menopause or after operations or treatments which reduce or stop the periodic pelvic congestion, women are less disturbed with sacral pains.

I agree with Dr. Lynch that much relief can be given younger women by procedures which aim to lessen pelvic congestion. Also I agree with the statement that about 25 per cent of backaches are associated with conditions outside the pelvis, and when a patient complains of backache I urge that the doctor should examine her back. Some of our most grievous errors have been due to this oversight.

TITIAN COFFEY, M. D. (1136 West Sixth Street, Los Angeles)—The symptom and complaint of backache in women is one of the most trying and obstinate conditions the gynecologist or obstetrician has to deal with. Doctor Lynch's careful study gives us many interesting points and much of value in helping these cases.

His record of relief of pain by operation in selected cases is very encouraging, but we all know a certain number of cases are not relieved by operation. Many cases with extreme retroflexion of the uterus never complain of backache at all, while others, especially women who have borne children, may have a well involuted uterus in proper position following confinement with apparently no pelvic pathology and yet complain severely of backache. In these cases we must look for another cause for the trouble and we find it is frequently due to some focus of infection elsewhere, either in the teeth, the tonsils, or an unrepaired cervix giving rise to an endocervicitis. A more frequent cause, however, in my opinion, is the strain put upon the pelvis at the time of confinement, especially in operative cases where a large fetal head has come through a small pelvis either after a long hard labor or the use of forceps. Here we get a stretching of the pelvic ligaments, a relaxation of the pelvic floor following the delivery and a loosening of the ileo-symphyses. This later is frequently shown and the small amount of displacement that takes place by the x-ray picture. These cases should be referred to the orthopedist for necessary corrective measures. Frequently the backache will be due to improper posture or to flat-feet.

Again the same condition comes in women with loose, flabby abdominal walls that give practically no outward support to the intestines, and here we have a condition of weight pressing upon the pelvic organs which increases the discomfort materially, if the pelvic floor is overstretched and loosened and not giving the proper support.

In studying these cases we must always keep in mind the important point that Doctor Lynch brought forth in the first of the paper that many other causes than pelvic congestion may give rise to this condition.

WALTER I. BALDWIN, M. D., 380 Post Street, San Francisco)—Doctor Lynch is indeed to be congratulated for the presentation of such a splendid statistical paper on backache in relation to gynecologic conditions. While his statistics bear out the impressions held by many orthopedic surgeons, it is valuable to have such a splendid piece of work to give such impressions a basis of scientific fact.

That the disturbance of pelvic circulation is fundamentally the final factor in the incidence of "pelvic backaches" seems logical and is an established fact.

That the character of the backache should be determined is also important. In acute lumbosacroiliac backaches due to trauma the symptoms are nearly always exaggerated by menstruation, and where the patient has been suffering from dysmenorrhea, oftentimes pelvic treatment may be imperative before a cure of the symptoms can be had.

The large number of backaches encountered and cured by correction of relaxation in the pelvic floor in Doctor Lynch's series is indeed instructive. I believe this condition has probably not been given sufficient attention by orthopedic surgeons, whereas a reference to the gynecologist might have produced the result. Undoubtedly a closer co-operation between the gynecologist and the orthopedic surgeon is greatly to be desired, but there will always be cases where such consultation is difficult

or impossible to obtain. In such instances it may be noted, for instance, that pain localized in the midsacral area is almost always traceable to an intrapelvic cause in women, and to prostatic and seminal vesicle conditions in men. The back pain is reflex in character and may be projected at any point along the reflex arc of the root innervation of the particular pelvic organ involved.

A marked deviation of the spine to either side should indicate that there was an orthopedic condition, at least co-existent.

One cannot but feel in Doctor Lynch's debt for much enlightenment on a very important subject.

THE DOCTOR IN INDUSTRIAL MEDICINE

By EDWARD F. GLASER, M. D., *San Francisco*

Industrial medicine is with us and has come to stay, and every day the industrial physician or surgeon is coming to a more and more prominent position in the profession.

Industrial medicine is not simply a field for the ordinary practice of general medicine and surgery; it is a development which, in its broader sense, takes in preventive medicine.

The industrial surgeon of today believes in and advocates physical examination of all applicants for work and the keeping of exact records of those examinations.

Industrial medicine has an active business side requiring organization.

There is a struggle on now to prevent industrial medicine becoming an industry rather than a science.

The business manager for doctors is a somewhat abhorrent idea to me. It seems the last word in commercializing the profession.

There can be no finer contribution to society than speedily to return to their occupations those who, unfortunately, are overtaken by industrial catastrophies.

The final test of an industrial surgeon is the value of the service he renders. The capacity of the industrial physician to serve is measured by the man himself, his preparation, his vision, and most of all, his attitude toward his job.

DISCUSSION by E. C. Fishbaugh, *Los Angeles*; Philip Stephens, *Los Angeles*; E. W. Cleary, *San Francisco*; C. W. Clark, *San Anselmo*.

THE more one thinks about the subject of the doctor and industrial medicine, the more complex and involved it becomes. It may seem simple at first if you only consider the doctor and his material interests, while in fact, and in the larger human sense, the question has other important factors besides the doctor—there is the patient himself, the industry and the public, and these interests are all entangled with each other. The medical brain is trained to seek out a pathological condition, to diagnose it, to treat it, to cure it if possible, and receive adequate compensation for so doing. Rarely does the medical brain recognize any duty beyond that—rarely does it acknowledge any duty to the community. It is somewhat unfortunate that medical men are, by reason of the intensive study that they give their profession and the necessary limitations in the training at the medical schools, seldom endowed with a broad comprehensive constructive grasp or viewpoint on questions. Doctors are taught to understand scientific facts, but not the fundamental and ordinary things of life, which is preparatory to saying that doctors are handicapped when they come in contact with the highly trained executives of a commission, a corporation, or an insurance company,

just as they are, generally, in dealing with the legal profession.

Industrial medicine is with us and has come to stay, and every day the industrial physician or surgeon is coming to a more and more prominent position in the profession. Industrial medicine is young, but it is growing by leaps and bounds, and promises very soon to become one of the leading, if not the leading specialty of medicine. But it will call for and will produce a highly specialized, a differently constituted and educated doctor from the old family physician.

The doctor who merely accepts employment to render emergency services in cases of accident, and often to protect the interests of the employers as to claims, is not an industrial physician in the truest sense. This type was the old-time doctor who was primarily a first-aid man. It was this class of medical men who earned the stigma of the "company doctor" and did not command the respect of either the employers, the employes, or of his professional colleagues. This type, while we may always have some of them with us, still is gradually growing less, and the industrial surgeon forging forward to the foremost rank of the profession, is honorable and is honored and is rich in opportunities for human service.

Industrial medicine is not simply a field for the ordinary practice of general medicine and surgery, it is a development which, in its broader sense, takes in preventive medicine (sanitation in prevention of disease, control measures for communicable disease, safety first for prevention of accidents)—it takes in the rehabilitation of the injured man, the restoration as nearly as possible to his former place in the economic world. It must consider the means for better health and contentment of the workers, means for increased production and decreased labor turnover. The industrial surgeon of today believes in and advocates physical examination of all applicants for work and the keeping of exact records of these examinations. This examination, if done with the proper thoroughness, is of great value to both employer and employee. The industrial physician comes into intimate contact with almost every branch of the industry, not only with the required medicine and surgery, but with the safety and welfare departments, and should with the employment office. But on the other hand physicians and employers must realize that industrial medicine is, in a measure, a compromise between the ideals of medicine and the necessities of business. Physicians have reluctance in accepting the materialistic viewpoints of employers, and conversely have difficulty in persuading employers to accept their professional points of view. In approaching the compromise, the fact should not be overlooked that medical service in the industries, to be of the greatest possible usefulness, must benefit primarily the working people, and then the benefit to industry naturally follows and the industrial surgeon justifies his existence. But we must recognize that industry exists, not primarily for ideals, but for the production of an output for a profit.

Industrial medicine has an active business side requiring organization. The corporations and insur-

ance companies must have an income and are often concerned in that more than in the patient or his efficiency. They must think of getting the injured man back as quickly as possible and with the least possible expense. Of necessity, they must continue organizing and concentrating, learning to give humane consideration, as they find it pays. Organizations that have grown up must make terms to deal with the small employer, with the result that, in having to give much service, it must make the good doctor work too cheaply or must employ doctors lacking in experience and, therefore, cheap in price.

There is a struggle on now to prevent industrial medicine becoming an industry rather than a science. Where the cold commercial side is considered and emphasized, doctors with ideals do not care to go into it, or, if they do, they find soon they cannot express themselves. They must put one side, ideals, for money consideration in the creating of efficiency of business rather than that of science. As a rule, the doctor has no business training and cannot compete in the world of business as in the world of science. Unfortunately, sometimes the doctor's ideals of giving humane service are changed by the pressure of commercialism and by our social system. He desires to meet the standards of his neighbors—must have an automobile, play golf, and have membership in clubs.

The business manager for doctors is a somewhat abhorrent idea to me. It seems the last word in commercializing the profession. Advance in medical science has been along the humane, and not the commercial line, and the great things in medicine have been done by individuals with a purpose. Still, the American people are running wild over organization. William Allen White said that if two Americans fell out of a balloon they would form some sort of a group before reaching the ground. In groups, too often, one or two big men who are outstanding are used for advertising purposes and then many small men to fill up. In groups there are always some men who have made their reputations outside the group, and with their reputations bring up the group standard. The group argument to employers may include more scientific service, but always does include cheaper medical service and saving of money. It has to be recognized that the financial prospects in industrial medicine are not always alluring. However, it is far better to have a fixed income under workmen's compensation than to have to send bills to injured and out-of-work employees who are unable to pay. The charging of the cost to industry, either directly or through insurance, is so sound that some of us wonder why it wasn't seriously thought of long before a short decade ago. The discerning doctor would strongly oppose a return to the old way of doing business. He recognizes that whatever benefits society places him, in the long run, in a position where he is the gainer.

Another factor in giving emphasis to the doctors' status in industrial medicine came out of the World War. Surgery for war wounds and surgery for peace wounds are not dissimilar—in fact, their genesis is the same. The quick attention, the instant use of the surgeon's instruments—these and other re-

sponses to urgent needs become reflected in fewer casualties and more repaired human beings. It has been recognized that the more specialized the treatment, the more dependable the outcome. This naturally followed the experience that can only come from doing the same class of work over and over and meeting the exigencies of such work.

So out of the horrors of war has come an appreciation of the relationship of war and peace in destroying or marring human beings. The purpose to restore one group to efficiency in order to fight can be followed to an even better end by planning to place the second group back into employment to resume their positions.

There can be no finer contribution to society than speedily to return to their occupations those who, unfortunately, are overtaken by industrial catastrophes. This gives the industrial doctor a unique status. If he is big enough to grasp his opportunities and follow the gleam, he will have the real satisfaction that follows work well done.

There are several outstanding factors or essentials that apply to the doctor in industrial medicine.

First—He must know his business. Absence of ability, of technical knowledge and failure to have learned from experience, leave behind in their wake too many losses that cannot be overlooked. This is especially so in industry, because society has laid down well-defined obligations for the treatment and care of injured workers, and the personal relation of doctor and patient has added to it a state dictum that is mandatory in character.

Second—The doctor in industrial medicine needs a human understanding, a healthy outlook on his fellow-citizens. He should realize his position is more than the one generally assumed between doctor and patient. He should realize the importance of winning men by fair treatment, by taking them into his confidence, so far as is possible, and by instilling into them self-reliance and respect for themselves.

Third—Care must be taken to eliminate the least taint of the charity idea in connection with surgical and medical treatment. Industry pays the bills, including the doctors' bills, but the hurt men make the painfully definite contributions of arms and legs and eyes and sometimes of life itself. The doctor must avoid any appearance of indifference or superiority to these generally super-sensitive patients. The injured man deserves a certain uniform courtesy, and he is sensitive to sympathy, which is valuable if of the wholesome type.

Fourth—The doctor in industrial medicine needs to keep up with the best in his profession, to find out the superior practices of others and to willingly give whatever may prove of gain in securing the great purpose of repairing the injured. He must be a student of prevention of disease and a follower of safety first in order to aid in the prevention of accidents.

The final test of an industrial surgeon is the value of the service he renders. The capacity of the industrial physician to serve is measured by the man

himself, his preparation, his vision, and, most of all, his attitude towards his job.

391 Sutter Street.

DISCUSSION

ERNEST CLYDE FISHBAUGH, M. D. (Pacific Mutual Building, Los Angeles)—Doctor Glaser has emphasized many of the salient features in the successful utilization of the doctor in industrial medicine. The doctor in industrial medicine is here to stay. Many physicians in California have already specialized in this branch of medicine. Others will have to give greater study and preparation for industrial work or be supplanted by more capable men.

The small compensation permitted by the state does not permit most physicians to specially equip themselves for this branch of practice. The small remuneration requires the employment of underpaid and oftentimes poorly trained assistants.

The business manager is obnoxious to many progressive and successful practitioners, but the definite remuneration is oftentimes most attractive to the poorly trained and less successful physician.

The personal qualifications as so admirably stated by Glaser are essential to the successful practitioner of industrial medicine.

This paper is timely and more such communications should be encouraged in order to advance the status of the present day industrial specialist.

PHILIP STEPHENS, M. D. (1136 West Sixth Street, Los Angeles)—The tendency toward commercialism in all phases of the industrial question is strong, and growing stronger each year. Groups, or so-called "service corporations," which are rapidly appearing in the field and competing with each other for business, are using, I am sorry to say, methods for fighting competition which apparently tend to squeeze out the individual industrial surgeon and his personal contact with the working man.

Doctor Glaser's plea for the old ideals, with their human touch, which under any and all circumstances must be preserved, is timely. We must preserve these ideals if we wish to hold the respect of ourselves, and all who must necessarily be served, and this great and good compensation law.

The traumatic surgeon or the general surgeon doing traumatic work must necessarily, under the present compensation law, get most of this class of work from either the industrial employer or the insurance carrier, and it behooves the industrial surgeon with special training along these lines to be a better general surgeon fundamentally, and the general surgeon to strive for more adequate knowledge and practice necessary to care for the injured man.

Many a good general surgeon falls far short in his effort to treat the industrial case, by reason of his failure to recognize certain fundamental principles, incident to what we might term ordinary routine, so absolutely necessary to make industrial work successful. They do not, and apparently will not, furnish accurate descriptive, anatomical records and reports of cases. Added to this is a total disregard for necessary promptness in rendering report at time of accident, with promptness thereafter in reporting progress of the case.

Another failure, as Glaser has cited, is due to the surgeon's lack of human touch with his patient. It is absolutely necessary for him to get the viewpoint of his patient, and he must use rare tact and judgment in the handling of this maimed and injured one who is making his sacrifice in the great onward rush of progress.

Doctor John Moorehead has said of the traumatic or industrial surgeon that he has long been of the opinion that cases of injury have not received the same care and attention accorded other surgical patients, and has often realized that a properly treated Pott's fracture or infection of the hand is a far greater manifestation of surgical art than the successful removal of an internal appendix.

E. W. CLEARY, M. D. (177 Post Street, San Francisco)—Doctor Glaser has given us a valuable paper. The doctor in industry should be a specialist in understanding

and knowledge of the problems peculiar to the medical care of workmen. There is, however, nothing in the position of the doctor in industrial practice which justifies his considering himself sort of super-specialist. The oculist, the physician, the dermatologist, the neurologist, the urologist, the orthopedic surgeon and, in a lesser degree, other specialties in the field of medicine should be recognized by the doctor in industry just as readily as if he were in private practice. A doctor may specialize in industrial practice and, at the same time, be well qualified as a specialist in any one of the above fields, but not in all of them at the same time. There is no greater menace to proper standards of industrial practice than the doctor in industry who treats every patient himself.

At this time the field of industrial surgery is particularly menaced by a pernicious type of organization which is aimed not at the achievement of any high degree of efficiency of treatment of the injured, but at the control of a large volume of work. The promoter of such an organization usually derives a profit from the activities of a corps of hack-workers whose handling of the injury is likely to be devoid of sympathy and low in efficiency. Such promoters contend that their position toward their hired staff is similar to the ordinary and time-honored relation of the chief to his assistant. The relations are, in no true sense, analogous. It is true that the chief pays his assistant a salary and charges the patient for the assistant's services, but the assistant has a very valuable additional compensation in the teaching which the chief gives him out of the wisdom of his more extended experience. The patient, too, is better served where he gets the benefit of the quick keenness of the younger man and the mature wisdom of the elder. The dealer in industrial medicine brings to his hired staff no valuable teachings. The doctor on such a staff gets nothing but his salary, and the patient gets, as a rule, a perfunctory service, because the man who renders the service gets less pay for it than even the small fee which the industrial schedule allows.

Wherever sharp business practice has lowered the fee of the doctor who actually serves the patient, whether such reduction of fee be by directly cutting the price below the accepted schedule or by diversion of a part of the recognized fee to an organizer or promoter who does not serve the patient, industrial surgery is degraded and the patient is wronged.

Glaser has mentioned the important results of the war surgery. There is at present a deplorable tendency on the part of many doctors in industry to ignore the better methods taught by the war experience wherever these methods are more expensive and time-consuming. I agree thoroughly that, granted proper training, the most important question concerning the doctor in industry is his attitude toward his job. Whatever his special field of experience, no doctor should take up industrial surgery unless he is willing and able to make industrial surgery a major consideration.

Finally, although the peculiar situations which occur are often difficult to handle and sometimes embarrassing, there is nothing in the relations of the doctor in industry which either justifies or makes necessary a departure from the proven and time-honored ethical standards of his profession.

C. W. CLARK, M. D. (San Anselmo, California)—The paper by Doctor Glaser is worth the earnest consideration of all physicians and surgeons of our state and nation, as industrial medicine is here to stay. Under present conditions the employer must protect himself, and the wage-earner must be protected, so compensation insurance has made adequate protection for both possible.

All goes well until the accident happens, then the physician is called. He then must decide the issue with the unfortunate one, as a physician to the patient; but, on the other hand, he must make detailed reports to the insurance carrier and compensation boards (details distasteful to the busy physician).

As the case progresses reports are constantly being required. These reports of necessity require time to fill out. The compensation is not sufficient for the best men to bother with. So in the course of events, the poorly trained, the hack members and the unscrupulous doctors take up the industrial side of medicine. They make out

reports and care for cases, or hire it done as if they had no interest in them.

The innocent victim resents this and, in turn, goes to his own physician, or he may go to some cultist, and the treatment he has received is reflected by him upon the profession at large, thus making a bad impression.

The cold commercial side of industrial medicine is not pleasant to most scientific men, so the best men in industrial medicine must not shirk, but assume the responsibility as any other. They must render the best possible service with the aim in view of getting the injured man back to work as soon as possible with the minimum of disability.

Carelessness and ignorance in treating injuries cause much more suffering and loss of time than is necessary in many cases. Thus, the insurance companies soon discover where they get the best service, and the unfit company doctor will, no doubt, soon be replaced by the specially trained industrial surgeon. There seems little doubt but that this will be developed into a specialty, as the others, in the very near future.

RADIOGRAPHS OF THE HEAD IN CHILDHOOD FROM THE CLINICAL STANDPOINT

By H. DOUGLAS EATON, M. D., *Los Angeles*

Radiography of the head in childhood is a valuable aid in diagnosis, both in chronic neurological and accident cases.

Up to the present time erosion of the sella is the only well-established evidence of pituitary disorder.

Roentgenologic evidence of pressure does not satisfactorily correlate with clinical findings.

DISCUSSION by E. B. Towne, *San Francisco*; Cecil E. Reynolds, *Los Angeles*; R. G. Karshner, *Los Angeles*.

DURING the last three or four years we have been making radiographs of the head in all children referred to the neurological department of the Children's Hospital in Los Angeles. The cases radiographed include both outpatient and inpatient cases, irrespective of a history of accident or injury. A comparison between the x-ray picture and the clinical findings has been undertaken, with the hope that it might lead to something of value, either in diagnosis or treatment. This paper is an analysis and discussion of our findings, and is to be considered as a preliminary report. Many interesting leads were opened up which will be the subject of further study.

The x-rays were reviewed and diagnosed without reference to or any knowledge of the clinical history of the case. The evidence seen on the x-ray plates was then correlated with the clinical records.

Roentgenology of the skull is a form of investigation, an aid in neurological diagnosis, that has advanced greatly in use and in value in the last few years. Prior to this time, the technical difficulties in taking satisfactory pictures, particularly in children, interfered with the use of this procedure.

The early radiographs of the skull were directed principally toward an attempt to study the sella turica. Oppenheim first called attention to the possibility of this work in 1899, and noted the changes produced in the sella by pituitary growth. Other early workers, as Erdheim, Kohler, Jaugeas, Fuchs, Beclere, together with some English workers, notably Holland, continued this work. In 1912, Harvey Cushing gave a complete discussion of radiographs of the sella in his work on the pituitary body

and its disorders. Fearnside, Keith, Gilbert, Scott, Finzi, Hampson, Johnson, and Schuller, as well as Heuer, Dandy, and Carr, have also written extensively on the subject.

During the last few years, while these special studies have been continued, there has been an increased appreciation and study of radiography of the skull as a whole. In the present paper, Schuller's classification, as found in the English translation of his work by Stocking, has been used. In our series of cases, however, the variety of recognized lesions was found to be much less than those included in Schuller's classification. The pictures were taken at a tube distance of approximately twenty-two inches and an exposure varying somewhat on account of the child's movements, but about two and one-half seconds. All the patients were under 14 years of age, and a great many of them under five, so there has been considerable difficulty in taking satisfactory pictures. No ventriculograms are included in this study. In all, 207 x-rays of the head were taken, and 101 of these, or roughly 50 per cent, we felt should be classed as normal skulls, from the radiological standpoint. All authorities, as mentioned by Schuller and Pacini in their review of skulls from the anthropological standpoint, recognize the fact that normal skulls show marked variations in size and shape. As guides to our estimation of size and shape, the relation of the fissures and the proportion between the vault and base were used. The writer does not feel competent to discuss Pacini's work on angles, in relation to the sella turica and pituitary disorders which was published in 1922 and for which he received the Leonard Research prize. In a review of the literature, however, many competent observers have been unable to confirm his work.

Anomalies, in shape and size of the skull, may occur as the result of disturbances in development. In our present series we found nine such cases, of which five were actual defects; one of these only being due to surgery. In two of these cases the records were incomplete. Of the remainder, four were girls and three were boys. Four of the cases showed extra sutures, in the frontal or parietal bones, without clinical symptoms. Two cases showed clinical evidence of increased intra-cranial pressure; a meningocele with an associated spina bifida and a megaloccephalus, hydrocephalic type, also showing a meningocele.

Ten cases of size and shape variations produced by disturbance in growth, this disturbance in its turn due to anomalies of the contents of the skull, were found. Three of these were microcephalies, seven megaloccephalies; the latter, with one exception, associated with hydrocephalus. Two of the three microcephalies were associated with impairment of mentality; in the last case, a malnourished child of a year's age, the x-ray was taken as part of a rachitic study. It is probable that this patient was also deficient. The megaloccephalies were of interest only in confirming other observers that the cause of this condition is practically always hydrocephalus. All these patients showed evidence of pressure clinically, indeed the x-ray was of only confirmatory value in the diagnosis. The seventh case of megaloc-

cephaly occurred in a boy of six. Here the diagnosis was a tumor in the mid-brain region. This patient showed optic atrophy, increased pressure of the spinal fluid, severe headaches, and projectile vomiting, with absence of evidence of infection. Operative procedure and autopsy study were refused.

There is an interesting class of cases due to premature synostosis of the skull. Various authors use various classifications for this group. Pacini, for example, quotes Luceas as using a classification involving twenty-four varieties of shape changes due to this condition. It seems to the writer, on the basis of the present study, sufficient to group such skull changes under the three headings of dolichocephaly (long head); brachycephaly (short head); turriccephaly (turret head), the latter preferable to the oxycephaly (or steeple head), which Sutherland and other writers have described.

Schuller quotes the following figures as normal for the obliteration of the sutures. The base at birth. Spheno-occipital at 13, facial at 30 to 35, and the remainder soon after 35, with the exception of the sagittal and coronal, which begin between 50 and 55. The cases in our series obviously show a great variation from these figures.

The definite etiology of this condition is not known. It has been suggested that it is the result of the pressure of the edges of the bone against one another, occurring in utero or during labor, or that it is due to a constitutional skeletal disease, such as rickets or syphilis. The clinical records of our cases do not warrant us in drawing definite conclusions on this point. Sutherland groups his cases as being congenital, acquired during the first few months, or acquired from the second to the sixth year, but throws no light on the etiology. In our series we found only three definite cases. One brachycephaly (or short head) and two turriccephalies (or turret heads). One of the patients was a definite mental defective, with a possible mild hypo-pituitary syndrome. Another was quite a marked case of rickets, while the third showed a defect in the occipital region, with a meningocele, a habit spasm and two cervical ribs; this child was normal mentally. None of the cases were proved to be luetic.

Schuller's class of changes in the skull, due to habitual attitudes or soft tissue anomalies, seems to the writer impractical. In our present series, we did not suspect any cases of belonging in this group.

Deformities of the skull in systemic diseases do not appear to be easily recognizable from a study of the x-ray plates alone, the method pursued in our present study. We did not recognize a case of cretinism, Mongolian idiocy, chondrodystrophy, or disotosis, which are the first four diseases listed by Schuller in this group. Rickets, we only felt sure of in two instances from the plates alone. It is to be recognized that our estimation of the age of the patient was from the plates, and that some cases would have unquestionably been called rickets, had we known the actual age. Schuller's other two headings of dwarfs or giants were not present in our series.

Turning to anomalies in the structure of the skull, we find our first group to be inflammatory conditions of the skull bone itself. We found no

cases of active osteomyelitis in our series; there was one case which seemed definitely luetic, though the child had a definite acute osteomyelitis elsewhere. No cases of tuberculosis of the cranium were recognized. One calcified area was found in a left temporal lobe associated with the clinical picture of a mixed, but largely sensory aphasia. The parents of the child refused further investigation, so the final diagnosis was not made. It is possible this may have been a calcified solitary tubercle. The literature indicates that tuberculosis and actinomycosis of the cranium are both rare conditions, while acute osteomyelitis occurs most frequently after wound infections.

Schuller's atrophic and hyperostotic changes in the skull were not found in our series, as is to be expected, for we studied only children's skulls. Acromegalic changes were also lacking in our series. Schuller further mentions neurotic atrophy, a condition with changes in the skull and skeleton he considers due to a trophic nervous disease. Other observers consider such a condition of little importance. Basilar invagination is another rare condition reported. This is said to be caused by undue weight of the skull added to improper development of the atlas or some nutritional disturbance in the bone surrounding the foramen magnum. The result is distortion and atrophy of the base of the skull. Virchow and Grawitz considered the etiology of this condition to be rickets, osteomalacia, or possibly hydrocephaly, but states there must also be a congenital anomaly in the formation of the skeleton. No cases of this sort were recognizable in our present series.

Tumors of the skull may be those involving bone or soft tissue. In our present series, five cases were found; all proved soft tissue growths save one. This case was in all probability a soft tissue growth, but operative and autopsy procedures were refused.

It is of interest to note that four out of five cases occurred in male children. In all five of these cases, the x-ray picture was of only confirmatory importance. Each case showed definite clinical evidence of increased intra-cranial pressure, and had focal symptoms.

Changes in skull structure may also be caused by injury to the skull. In our present series we found eight such cases. In all the cases but one, there was a definite history of an accident; the one exception was a child of eighteen months, and it seems probable there had been an unnoted injury. In fracture cases, radiographic study is of distinct importance, both in diagnosis and in the determination of treatment. In 4 or 50 per cent of these cases, we found so-called general erosion or convolitional atrophy markings—two generalized, one occipital only, and one frontal and occipital. Two we called first degree, and two second. The ages of these cases were: First degree, four and five; second degree, six and nine. We will discuss these findings a little later.

As we mentioned early in our discussion, a great deal of work has been done on the radiographic study of the sella. Spurred on by the hope of being able to recognize disorders of the pituitary, numerous writers have discussed varying methods of technique, and have drawn what seems to the writer

decidedly overenthusiastic conclusions from questionable evidence.

Obviously, the determination of variations from normal must be preceded by a determination of the normal. In the recognition of a normal sella, we find widely differing opinions. Someone has said that all scientists are divided into two schools—the “lumpers” and the “splitters.” This certainly seems true in regard to descriptions and classifications of the normal sella. The “splitters” school has listed some seven hundred type variations; the “lumpers,” three. The writer prefers the “lumpers” for the purposes of the present discussion.

Gordon and Bell conclude that there is no definite shape of the sella in normal children. These observers attempted to classify the sellas examined into three shape groups, but not only found it extremely difficult to fit a majority of cases in these groups, but note that the groups, when determined, are of no clinical value. The same writers conclude, as the result of their study, that no definite relationship exists between the size of the head and the size of the sella. They did find the sella in girls to be larger in both height and length than in boys. They also found a fairly definite relationship between height and length, and noted that the most rapid growth in the sella took place in the first and second years. I have quoted their findings at length, for they seem to me rational and based on satisfactory evidence. Knox, writing recently in the *British Journal of Radiography*, on the other hand finds a definite relationship between the size of the head and the size of the sella. His apparatus is most elaborate, and the opportunity for technical error is so great that the writer questions the value of his conclusions.

In our present study we did not attempt any elaborate measurements or shape-grouping, for the reason that we considered them valueless. We grouped our cases as (1) large, (2) small, (3) closed in, the latter being the type where the anterior and posterior clinoid processes seem to roof in the sella; here, of course, the angle at which the plate is taken is of great importance.

Of large sellas, we found eight. In contradiction to Gordon and Bell, all of these but one were found in males. The age incidence was from four to twelve. Six of the cases were between eight and twelve. Two of the eight cases were classed as idiopathic epilepsy; there were three cases of brain tumor, one of multiple exostosis; one of epilepsy due to birth injury, and one of hydrocephalus. No signs of erosion of the sella were found in these cases. Inasmuch as these sellas showed a general enlargement, the possibility that they were simply broadened by pressure seems to be ruled out. In this group of large sellas, no evidence was found of relationship between the size of the sella and the clinical picture.

In the small sella group, we had six cases, evenly divided between the sexes. One of these cases was a normal child, studied on account of an accident. One case had a sixth nerve paralysis, etiology unknown. The other four cases were deficient mentally, one a hydrocephalic, one a hemiplegic, and one seemed pretty definitely a hypopituitary case, complicated by an evident birth injury and spastic paralysis.

Our so-called “closed in” groups consisted of ten cases, again equally divided between the sexes. The age varied between two and eleven, with no definite age incidence. Five out of ten of these cases were definitely deficient, two were classed as idiopathic epilepsy, one had a fractured skull, but otherwise was normal. One was a case of encephalitis lethargica, and one a case of progressive muscular dystrophy. Six of these cases showed definite clinical evidence of increased intra-cranial pressure, four showed signs of focal irritation. Only one of these, an imbecile, showed signs of deficient pituitary secretion. Surely, from the clinical standpoint, large, small, or closed-in sellas, cannot represent any definite pituitary syndrome.

It is to be noted further that, of 207 heads studied, only twenty-four, or 11 per cent, showed sufficient variation in the sella to be considered remarkable. Of these twenty-four cases, 2 or 8 per cent showed clinical evidence of pituitary disorder. Possibly this means that there is a relationship between abnormalities in bony structure and disturbances in the gland. I do not feel, however, that we are justified in any conclusion at the present time other than that evidence of erosion indicates tumor growths. Clinically, these cases, with several others showing clinical evidence of pituitary disturbance, have been treated with pituitary by mouth and hypodermically without results.

Schuller recognizes many possible causes for calcification in the skull. Aside from one case already mentioned, possibly tubercular in origin, no cases of calcification occurred in our series. Calcification in the pineal gland has occurred infrequently in my adult cases.

Changes of the skull, in consequence of intra-cranial disease, occurred but once in the present series. In a probable slow-growing mid-brain tumor previously described, there was some circumscribed thinning, with evident absorption of bone.

Under changes in the skull, due to chronic excessive intra-cranial pressure, Schuller mentions the following: generalized erosion, commonly spoken of as convolutional atrophy, shape changes, widening of the sutures and venous canals, and thickening of the skull. Chronic hydrocephalus, tumors, cysts, tubercles, gummata, are the usual diseases causing erosion of the inner surface of the skull. Diseases causing a rapid increase produce, in Schuller's opinion, roughness unrecognizable by radiography. A slow increase in the contents of the skull produces a mottling with numerous roundish light areas, local or generalized. These markings are said to appear within a few weeks of the onset of clinical symptoms, and in childhood are said to be seen earlier and to a greater degree. Schuller's conclusions in this regard are quite sweeping. He states: “Roentgenologic proof of erosion of the inner surface of the skull is a sure sign of an increased intra-cranial pressure which has existed for a long time.”

In our study of this phenomenon, we were forced to some sort of classification, and consequently grouped our cases as showing first, second, third, or fourth degree of general erosion. It is realized that such a classification is an arbitrary one, but as all

the x-rays were re-read in two sessions, it is felt that the readings were reasonably consistent.

In our first degree series there were twenty cases in which we had complete records. Of these, eight were girls. There was no particular age-grouping. The cases ran from two to nine. Twelve were between five and nine. Eight of the cases were mentally deficient; two were retarded. Three were fractures occurring within ten days of when the plates were taken. The remainder showed varying degrees of birth injury or epilepsy or both. These clinical findings are not incompatible with Schuller's idea of increased pressure. It is to be borne in mind, however, that over 50 per cent of our x-rays did not show the convolutional markings to any degree, yet their clinical diagnoses ran practically the same as those in this first degree convolutional pressure group. Three of these cases were proved to have increased pressure clinically.

Our second degree cases numbered twenty-three, fourteen males. Twelve of these cases were definitely deficient, there were three fracture cases and, curiously enough, one rachitic case. A progressive muscular dystrophy, a dysuria, and a cervical Potts seem out of place in an increased pressure grouping. Six of these cases showed clinical evidence of increased pressure.

The third degree cases numbered eight, of whom seven were boys. Only two of these cases rated mentally deficient, another case of rickets occurred, there was one recent fracture, a cervical Potts, a brain tumor, and a hydrocephalus. The other case was a habit spasm with a double cervical rib. Five of these cases showed clinical evidence of pressure.

Our fourth degree cases, of whom we had complete records, numbered but three, all boys. Two of these cases were brain tumor cases with clinical evidence of generally increased intra-cranial pressure, as well as signs of focal irritations. The other case was one of osteomyelitis of the tibia. In this case clinical evidence of pressure—indeed, of head disturbance—was lacking as far as our records go. The age incidence in the last two groups did not vary from that in the first and second.

It is suggested to the writer's mind that convolutional markings, so-called, cannot be explained solely on the theory of increased long continued pressure. General nutritional changes seem a possible etiological factor which it is hoped to investigate more fully in a further study.

Shape changes, apparently due to increased pressure, were rare in our series. Only one such case was noted—a male child of three months, who had pyloric stenosis. This case also showed suture changes, but clinically gave no evidence of increased intra-cranial pressure, if the vomiting was to be explained by the pyloric stenosis. No neurological study was made of this case.

Changes in the sutures occurred in eleven of our cases. Thickened skulls in seven. Widening of the venous canal was found in twenty cases. Widening of the venous canals and suture changes were found together in but three cases, while in none of these cases were more than two of Schuller's signs of generalized increased intra-cranial pressure found in the same case.

The clinical findings did not correspond very satisfactorily with the x-ray evidence. For example, in the class of widening of the sutures there were six cases out of twenty who presented no evidence whatever of any increased intra-cranial pressure or anything remotely allied to it.

In the thickened skulls, one case was a normal child at least as far as his head was concerned. Suture changes seemed to be more constantly associated with mental conditions, for in this group every case but one showed mental symptoms. This one case was the one previously mentioned which was diagnosed as pyloric stenosis; it seems possible that a brain condition may have co-existed. The child did not survive, and no autopsy was permitted. Of the total number of cases in these last three sub-grouping, namely, widening venous canal, suture changes and general thickening of the skull, thirty-nine in all, definite clinical evidence of increased intra-cranial pressure was obtained in eight only; clinical evidence of brain irritation or deficiency in twenty-three.

When the writer undertook this study he rather expected to reach some definite conclusions. The study has served, however, rather to open up interesting fields for further work in correlating radiological with clinical findings.

CERTAIN CONCLUSIONS SEEM WARRANTED

1. Radiography of the head in childhood is a valuable aid in diagnosis, both in chronic neurological and accident cases.
2. Up to the present time erosion of the sella is the only well-established evidence of pituitary disorder.
3. Roentgenologic evidence of pressure does not satisfactorily correlate with clinical findings.

I ask that you consider this a preliminary report, for there are many points which further study will, I am sure, elucidate. My deep appreciation is expressed to Rolla G. Karshner for his co-operation in this study.

1136 West Sixth Street.

DISCUSSION

E. B. TOWNE, M. D. (Stanford University Hospital, San Francisco)—Dr. Eaton's interesting paper brings up many points for discussion. I will confine myself to two x-ray findings, which are of importance in neurological surgery.

Eaton found in this series only one example of calcification in the brain, and he has infrequently seen calcification of the pineal gland of adults. Our experience is quite different. R. R. Newell reported the findings of the Department of Roentgenology of Stanford University Hospital for the year 1922. There were nine cases of brain tumor which were microscopically verified, and six cases which were not verified, but which were, on the clinical findings and course, undoubtedly brain tumors. Six, or 40 per cent, of the fifteen tumors were localized by the x-ray because of calcification. Two of the calcified tumors were in children aged 6 and 10 years. Two other calcified lesions were demonstrated in children—a teratoma invading the cranium, and an inspissated abscess of the parietal cortex. Forty-five per cent of adults in Newell's series showed calcified pineal glands. Newell attributes the high incidence of pineal calcification entirely to improved x-ray technic.

I agree with Eaton that slight or moderate convolutional atrophy of the skulls of children needs clinical confirmation before it should be interpreted as indicating in-

creased intra-cranial pressure. I have observed several children who were suspected of having brain tumors because of epileptic attacks and convolitional markings, who have shown no further evidences of increased pressure after three or four years. The very marked examples usually do have other signs of pressure. The most advanced atrophies which we have seen have been in two 12-year-old boys; one of them had an extreme turriccephaly, and the other an enormous meningeal tumor weighing 345 grams. Both of them had normal optic disks. I feel that marked erosion of the inner table of the soft cranial bones of children is a valuable sign, not to be discounted by negative optic disks.

CECIL E. REYNOLDS, M. D. (Pacific Mutual Building, Los Angeles)—This paper is of great value and interest in a somewhat neglected field. In my own practice, x-rays of the skull are taken almost as a routine, and out of a very large number I will direct my comments, especially to such as illustrate the points brought out by Eaton in regard to cases that are clinically most obscure.

In regard to microcephaly and synostosis, I adduced reasons for believing that many such cases were due to intra-uterine encephalitis or basal meningitis during early life. Either of these conditions will cause an excess of extracerebral fluid, with consequent shrinking of the cerebrum in the case of meningitis, the excess of extra-cerebral fluid being secondary in the case of encephalitis. In both instances there is a diminished expansile pulsation of the brain, which is a necessary factor in the proper development of the skull, and maintenance of the open suture. Benefit from operation in such cases can only be expected from differentiating the meningitic from the encephalitis and treating early. Primary encephalitis is obviously most unfavorable. In non-inflammatory cases, by the formation of new sutures, I first obtained benefit in 1912 (Southern Calif.: Pract.: May, 1914).

The study of osteoporosis or convolitional markings is of great importance in epilepsy. It cannot be too much emphasized that the brain is apt to respond to pressure by fits when that pressure is insufficient or too intermittent to produce the coarse clinical signs of pressure. Most gratifying results have ensued in my experience from taking due note of the fact that x-ray reveals that a chronic pressure has at one time existed. Take, for example, occult hydrocephalus, a fairly common cause of so-called "typical essential epilepsy." If it remains "internal" it is most likely to show osteoporosis, especially when there is no pathological enlargement of the cranium. If it is primarily "external," no help will be given by x-ray, but many cases of external hydrocephalus have commenced as the internal variety, being later converted by a giving way of the tela choroidea, and these will show convolitional markings. Moreover, the fits of external hydrocephalus are more easy to diagnose clinically than those of the internal, hence radiography has a useful place in epilepsies from these causes where there is no enlargement of the skull.

In regard to the sella turcica, information may be obtained which is inaccessible in any other way. Two most striking cases will illustrate:

Mr. J. W. T. consulted me April, 1922, for petit mal with prolonged automatism since August, 1918. X-ray showed marked closure of sella turcica. He was fed on Burroughs and Wellcome pituitary, and had no attacks for a year after May 22, although before he sometimes had several a week. Then the gland extract was stopped and he soon after had an attack. Recommenced pituitary, and he remained well for another year, until it was stopped when he had another attack. He has remained well again since resuming the extract.

L. L. had severe whooping cough at the age of 7, and thereafter did not grow an inch in four years and had fits several times a week and clonus of the neck (nodding) nearly every morning. X-ray showed sella very enclosed and small. Pituitary extract had no effect. Suboccipital deduralization (complete) performed, and during the following year he grew a foot in height and has had no fits for two years. I do not attempt to explain this; it is interesting, in view of the very definite x-ray findings.

In regard to tumors, we have had some deep gliomas revealed by their slight calcification around the margins before confirmation by ventriculography. We have also found marked osteoporosis in some Mongolian defectives,

but decompression in one such case was not followed by appreciable benefit. Very extensive calcification of the falx cerebri was revealed in one case with mental symptoms. In numerous cases changes of the membranes and local collections of fluid have been revealed.

From what has been said today, and from what has been written in the past, it is evident that there is a fertile field for radiography of the head beyond the more obvious manifestations of fractures and erosions by new growth.

R. G. KARSHNER, M. D. (1136 West Sixth Street, Los Angeles)—It is my privilege to have reviewed the radiographs upon which Dr. Eaton's paper is based. In many of the cases the failure to elicit pathology from these radiographs may be excused because of the technical inadequacy of the examination of the individual patients. The great majority of the radiological reports were rendered solely upon one or two lateral views of the head, not always of the best quality. Consequently, many of the examinations were passed as negative when careful radiography using an exacting technic with modern apparatus would have demonstrated changes from the normal. In other words, radiography of the head requires the expenditure of time and effort, which is not always compatible with the accomplishment of the volume of routine work that passes daily through a busy children's clinic somewhat handicapped by lack of direction, personnel, and equipment.

Eaton states that no case of cretinism, Mongolian idiocy, chondrodystrophy or dysostosis was recognized from the films. To my knowledge, more than half a dozen cases of chondrodystrophy have passed through the clinic, and have been diagnosed by the x-ray during the period covered by this series of cases. It is too well established that changes in the base of the skull in chondrodystrophy are demonstrable by the x-ray to challenge controversy. Failure to find such changes in this series is due to failure to include the cases in the series, or failure to make the proper roentgen examination of the head.

Dr. Towne mentions the report of Dr. Newell, regarding calcified pineal glands. In our private work we have noted a decided increase in the incidence of such findings, due to the employment of improved technical methods which were not afforded in Dr. Eaton's series.

Dr. Eaton seems justified in his third conclusion. Certainly, the presence of convolitional markings in the heads of childhood are not in the light of our present knowledge of the same clinical significance as the same findings in the skull of an adult. Many explanations suggest themselves. The cause, however, does not as yet seem clear.

DOCTOR EATON (closing)—In closing the discussion, I wish to re-emphasize my previous statement as to the technical difficulties in our series. Since reading this paper, we have had three cases of chondrodystrophy recognized by radiography without access to the clinical records. The previous cases mentioned by Dr. Karshner must have been omitted because of imperfection in the head film.

During the coming year we are planning to continue the study, and hope to have some conclusive data on one or two of the questions opened up in the present study.

Nu Sigma Nu Fraternity (reported by Miley B. Wesson)—During the course of the recent meeting of the California Medical Association, five acquaintances discovered that four of the group were members of the Nu Sigma Nu Fraternity, and it was suggested that a dinner party be given. A notice was posted on the bulletin board, and the following twenty-four men assembled. The manager of the Lodge simply pushed tables together and selected from the regular menu card a dinner which I have never seen equaled at any banquet.

It was unanimously decided to make this dinner an annual feature of the state medical meetings. Those present were: Stanley Stillman, William E. Stevens, Harry Alderson, George D. Culver, Morton R. Gibbons, J. Marion Read, Carl L. Schaupp, Percival Dolman, Curtis E. Smith, John H. Woolsey, Miley B. Wesson, San Francisco; F. S. Dillingham, Peter O. Sundin, Los Angeles; C. B. Jones, Sacramento; A. M. Meads, Sumner Everingham, Frank S. Baxter, Oakland; Robert T. Legge, Berkeley; A. L. Brankamp, Banning; Joseph H. Shaw, Santa Rosa; Keith S. McKee, Bakersfield; D. H. Murray, Napa; Irvin H. Betts, Visalia; Fred R. De Lappe, Modesto.

THE INFERIORITY COMPLEX AND ITS PSYCHIATRIC SIGNIFICANCE

By HAROLD W. WRIGHT, M. D., *San Francisco*

If a child survives the periods of infancy, childhood or adolescence without becoming inoculated with the inferiority complex, what happens later has little chance of fixing such a complex to any serious degree.

The survival of the physically inferior now does not conflict greatly with the interests of the herd, for the complex modern world has a place for all of them in its industrial scheme, providing they are psychologically fit to cope with their environment.

In some instances this complex is only the result of lack of proper vocational guidance and the adolescent or young adult becomes a misfit in the busy world, with consequent discouragement and failure. There must be many cases of this sort.

Illustrative case reports.

Neuropsychiatry has now reached a crossroads or turning point in its development. Its field of work, although broader now, is being encroached upon more and more by psychologists who have no medical education, some of whom are very superficially trained in their own line, some actually charlatans.

DISCUSSION of the type that brings out important phases of an important subject by Ross Moore, Los Angeles; Aaron J. Rosanoff, Los Angeles; Ray Lyman Wilbur, Stanford University; V. H. Podstata, Livermore; Christine M. Leonard, Los Angeles.

SINCE the beginning of any social contact of human beings this complex has existed. It began as soon as man had the opportunity to compare himself or be compared with other men, as soon as the interests of one conflicted with those of another, as soon as one surpassed another in any way. Thus was fear and jealousy bred, fear of others and fear of self.

As time passed and human relationships, both in the family unit and in the larger unit of community life, became more difficult this complex became more subtle and refined into forms less obvious to the sufferer from it.

The survival of the fittest, in the physical sense, was secured, and the non-survival of the supposedly unfit was made sure by very primitive methods in the days of savagery and barbarism; but later on the unfit, in the physical sense of that term, have more and more been enabled to survive. The survival of the physically inferior now does not conflict greatly with the interests of the herd, for the complex modern world has a place for all of them in its industrial scheme, providing they are psychologically fit to cope with their environment. Consequently, it is no longer true that this complex is inevitably associated with physical inferiority; it now arises much more from post-natal psychological impressions.

This post-natal psychological causation can, and usually does, begin very early in life; in infancy or early childhood. If a child survives the periods of infancy, childhood, or adolescence, without becoming inoculated with the inferiority complex, what happens later has little chance of fixing such a complex to any serious degree. This complex must be considered as something inoculated into the child by parents, teachers or other adults, or by fellow-children. Because of the impressionability of a child, all later tendencies have their roots in the plastic years. This is but an obvious truism, though one which is

frequently forgotten in favor of laying the blame for everything on heredity.

Naturally, such complexes can be induced in a variety of ways which may be summed up in such descriptive terms as excessive "spoiling" with inculcation of dependency on father or mother, unwise and needless repressions of natural and innocent activities, nagging and scolding, physical cruelty and unfair punishments, ridicule and unfavorable comparisons with other children, marked social inequality of opportunity, high-handed moral attitudes on the part of adults toward faults or habits in the sexual sphere without calm explanation and frankly helpful advice, pessimism and irritability in the home atmosphere which reveals to the child parental inferiority and failure. All these influences tend to induce depression and loss of initiative with lack of fearless and confidential relations between the child and the adult world. In some instances this complex is only the result of lack of proper vocational guidance, and the adolescent or young adult becomes a misfit in the busy world, with consequent discouragement and failure. There must be many cases of this sort.

Undoubtedly, children react differently to such influences according as they are constitutionally vigorous or not, according as they are naturally inclined to be introverted or extroverted, aggressive or shrinking in nervous makeup, physiologically speaking. Consequently, in the aggressive type the psychoneurosis, which grows out of an induced inferiority complex, will differ in symptomatology from that which occurs from the same cause in the introverted type. And so we have later on the psychoneurosis with paranoid symptoms or with criminal behavior representing a defense against inferiority, and the psychoneurosis with depression, anxiety, diffidence and withdrawal from healthy social contacts; or the psychoneurosis with symptoms of a very complete withdrawal from the conflict and a satisfaction in solving the personal problem through hysteria. As any of these psychoneuroses progresses or as some other factor comes into play to break down the general nervous resistance (a toxic, exhaustive, or an organic factor), there may develop a psychosis of the paranoid type, the manic-depressive type, the schizophrenic precox type, or the hysterical type. Thus we may consider that psychoneuroses and psychoses are sometimes phases in the progress of the same fundamental complex—stages in a long-standing disorder of the personality.

ILLUSTRATIVE CASE REPORTS

1. A male child of intelligent parents witnessed from infancy the frequent quarrels between his parents, the father being at times violently irritable, due to chronic physical ill health and financial strain. As the child grew older he was always aware of some impending disaster in the home, which usually had an atmosphere of gloom and anxiety. An example of fear, doubt and indecision over any new problem was set before him by the father, who also vented his irritability upon the child for any trivial thing, making him feel thereby that he did not amount to much, that he was stupid, etc. The boy grew to love solitude and to shrink from taking part

in social pleasures with other children because he felt depressed, and his ill-concealed depression was misunderstood by the other children who thought him unfriendly. As time went on he developed the habit in his turn of showing irritation at trifling events and of putting off decisions because of his lack of self-confidence. By the time manhood was reached he had no definite plans for his future career, was inclined to take the path of least resistance, often being moody and changeable in purpose. He felt that other people thought him queer, that others were unfriendly. Not being very robust in physical constitution, he became asocial rather than actively anti-social. Energies of a physical sort found no outlet in healthy sports, and being shy of women he had difficulty mastering the habit of masturbation, which began at adolescence. He was afraid to marry. So he drifted along in a routine occupation much beneath his natural intellectual ability and, of course, was not satisfied in his work. He was sensitive to the criticism of his fellow-workers and his superiors to an extreme degree, and also jealous of those who were more successful than he. Middle age arrived with a realization that he was still a failure, and by the time he was 48 he had a severe attack of depression resembling the involution type of melancholia.

2. A young woman gives the history of having been brought up to think that anything connected with the sexual instinct was most deplorable. In childhood her first questions about such matters were side-tracked and received by her mother with embarrassment and evasion, also rebuke. As she matured she became very shy of boys, but her curiosity and thoughts along sex lines continued quite active. She felt that her thoughts were very wicked and that she must be different from other girls, for they did not appear to be bothered by such matters and seemed quite at ease with boys. She grew more and more self-conscious and diffident in trying to express herself in the social world. Naturally, offers of marriage were slow in coming. However, after a time she became infatuated with an unscrupulous fellow who seduced her. This experience produced a profound depression with anxiety symptoms, followed after some weeks by an acute excitement in which she had delusions of persecution, spoke of herself as the Virgin Mary, showed flight of ideas with prolific talk, and had to be confined in a psychiatric hospital. There she ran the typical course of an acute mania and recovered with a residual state of emotional apathy and indifference toward her family, to whom she has not yet been able to adjust herself. There also ensued a certain lowering of her standard of morality.

Many more illustrations of this complex might be given if time permitted. We are all familiar with the fact that hauteur and reserve and also their opposites, undue familiarity and aggressiveness, may cover up a feeling of inferiority or inadequacy, and that supposed modesty and humility may at times be a cloak for "cold feet." The two cases reported serve to indicate that a psychoneurosis or a psychosis is a

condition of gradual onset and progress, and may arise from preventable psychological causes.

PREVENTIVE WORK IN NEUROPSYCHIATRY

It is quite apparent that these disorders are productive of much unhappiness, friction and failure, to say nothing of more serious consequences. They affect adversely the home life and industrial life and all with whom the individual comes in contact. We who work in the field of neuropsychiatry have some workable knowledge of the mechanism of these disorders. Indeed we have quite a store of theoretical knowledge, and we can have a much greater store of practical information which can be made available to parents and teachers for prophylactic purposes, provided we continue to get at the roots of these disorders in all patients that come to us.

Neuropsychiatry has now reached a cross-roads or turning point in its development. Its field of work, although broader now, is being encroached upon more and more by psychologists who have no medical education, some of whom are very superficially trained in their own line, some actually charlatans. The field is also invaded by all sorts of religious cults and narrow-minded philosophers. On the other hand, the citizens who are more discerning are looking to the medical profession for a solution of the problems of crime and juvenile delinquency, and many educational problems. They are ready and eager for our assistance, and often expect of us the impossible; and yet we have much to give them which we do not make clearly available.

We may well consider at this stage in the development of our specialty which, by the way, is so broad that it is inappropriately termed a "specialty," where to place the emphasis in medical education and research; whether to give less attention to refinements in the diagnosis and treatment of organic nervous disorders which we know have already wrought permanent pathological changes and more attention to the early detection of functional nervous disorders and the early treatment of them by sound methods; or to neglect the psychopathology of children and adults while worrying over tables of height and weight and nutrition or the chemistry of the cerebrospinal fluid.

We might consider also how we may formulate our growing knowledge of functional disorders of the nervous system so as to make it helpful to parents, teachers, and college students. To a slight extent this is being done here and there. It is not to be expected that many medical students can be made interested in neuropsychiatry if their vision of future work in this field is narrowed down to the palliative treatment or passive care of the end-results of chronic organic disease; but if their vision can be enlarged further by presenting to them the dynamic, social aspects of psychiatry in an attractive way, there should be no difficulty in providing this field with enough well-trained and enthusiastic laborers.

870 Market Street.

DISCUSSION

ROSS MOORE, M. D. (520 West Seventh Street, Los Angeles)—It occurs to me to wonder whether the manifestations of the inferiority complex so clearly and broadly sketched by Wright are not after all really conservative.

I am not saying that they ought to be conservative. Theoretically they ought not to exist. In the future they will not exist practically because then there will be enough square pegs for all the square holes and square holes for the square pegs. Our growing knowledge will make this possible and our growing tax rate will make society demand it. For the present the psychopathically inferior will have to remain largely ignorant of his own inferiority and retire within his own psychosis.

Methods of training the handicapped child are fairly far advanced both in school and home. There is much enthusiasm in both places to help these unhappy ones. But there is no enthusiasm in the home when it comes to recognizing and admitting the poor material out of which the child is made. I believe this admission will be forthcoming only when we force its presentation and at the same time show more clearly the social means available for its proper handling.

Stressing heredity is still the important thing.

AARON J. ROSANOFF, M. D. (Westlake Professional Building, Los Angeles)—The inferiority complex probably plays a part in the mechanism of all mental disorders of a functional nature. It is strange that no one had chosen it as a topic for special emphasis and discussion, as Dr. Wright has now done.

It is always a difficult matter to distinguish clearly hereditary or inborn factors from acquired ones. Dr. Wright deserves credit for pointing out that one factor in the bewildering complexity of mental mechanisms, namely, the inferiority complex, is always an acquired one. The significance of this is obvious for the practice of mental hygiene.

Wright has said that the field of neuropsychiatry is being encroached upon by persons without medical training. He seems to regret this fact, and I am in sympathy with him as far as this encroachment is by incompetent or insincere persons, whether with or without medical training. But I rather welcome all possible participation by psychologists, criminologists, social workers, teachers, and others. In my opinion, without such participation the larger ends of mental hygiene can never be attained, as they are beyond the unaided powers of the mere handful of neuropsychiatrists; and this not only because they are a handful, but also because some phases of the work require training and specialization which is not a part of medical curricula or practice.

RAY LYMAN WILBUR, M. D. (Stanford University, California)—As a rule all of the children in a given family are exposed to practically the same conditions at home, on the street and in the school. It hardly seems complete to me to lay all of the stress upon certain happenings of childhood in the child that later on shows certain psychopathic peculiarities. *I have the feeling that the psychopathologists in working backward for explanations of their patients are apt to forget the ability of many individuals to throw off environmental effects that disturb those who are mentally tainted.* All young people have a difficult problem in getting on with the adults with whom they are associated. It takes a good deal of skill on the part of a child to understand just what the parents want, why they want it, and why they vary so in their demands. I cannot escape the feeling that while the inferiority complex is of great significance it is the individual rather than the experience that is the predominating factor in turning mental reactions in an abnormal direction.

Dr. Wright's paper strikes me as particularly interesting and of real significance in developing a proper approach to the problems of the neuropsychiatric individual.

V. H. PODSTAT, M. D. (Livermore, California)—The paper of Dr. Wright leaves with me three impressions:

First—A keen appreciation of the endeavor of Dr. Wright to impress upon the medical profession the great influence of the early surroundings upon the moulding of the child's personality. Much has been written upon this topic, but the body of the medical profession has failed to be impressed by the facts. A small proportion of the physicians in general practice has been unduly influenced by the extremists in the psychoanalytic school; hence, embryonic and infantile sex conflicts and complexes. The larger number of physicians either cling to the ultra-

conservative views or are more or less bored with the entire topic of study of behavior. Wright's paper is practical and worthwhile to every physician seeking to be of service to humanity.

Second—The limits of the paper are undoubtedly responsible for his taking up the "inferiority complex" and not reaching out to cover the entire topic of the common prevailing depressive tendency. The "inferiority complex" is only one common expression of such depressive tendency. There are many fears, obsessions, doubts, worries, and anxieties growing from out of the soil of the fundamental depressive tendency which are not identical with the "inferiority complex." I trust that someone may concisely, yet effectively, present this "Multitude of the Unhappy."

Third—No physician will question that Wright did well in emphasizing environmental psychogenic factors. However, they are not alone in the capacity to produce a tone of depression or the actual feeling of personal inferiority. Also, among the psychic causes it need not necessarily be the early surroundings of the child. There are many unsolved problems carried by adult people like millstones about their necks, producing perceptible and prevailing mental depression, also a variety of feeling of inferiority. Some of these unsolved problems may have been repressed below the level of consciousness, but that is not necessary to make them effective. Among the physical causes, toxic influences and endocrine unbalance should be mentioned. In short, every case of "inferiority complex" is an individual case compelling careful study of both physical and mental etiology.

CHRISTINE M. LEONARD, M. D. (1401 South Grand Avenue, Los Angeles)—I was present at the time Dr. Wright presented his paper, and enjoyed it. We had found in our study of children at the Child Guidance Clinic that the feeling of inferiority is a large factor in behavior problems. We have noted inferiority complexes with physical, intellectual and social bases. The child frequently attempts to compensate, and failure in this often results in overcompensation and definite maladjustment. These children are often problems both in the home and in the school. Physically they feel inadequate and do not take part in play with their companions. Sometimes they will not fight, swim or enter into active games; they are unable to compete successfully with their classmates. Because of feelings of social inferiority, they often will not bring their friends to their homes to play.

In children who have inferiority complexes the sense of self-confidence and power is missing and we have developed then, either a quiet, depressed, perhaps sensitive and reticent child (introvert type), or an egocentric, overcompensated child who is perhaps the bully of the neighborhood (extrovert type). Are we not warranted, then, in uncovering this complex early and helping the child overcome what Dr. Wright so clearly shows in his paper to be a large factor in adult maladjustment?

Witter Water—This is a product put out by Witter Medical Springs, San Francisco. It is advertised as a remedy for "high blood pressure." The public is warned of the tragic consequences of this condition and given the usual line of testimonials, telling how Mrs. A. with high blood pressure and one foot in the grave took Witter Water and recovered. Among other constituents, Witter Water is claimed to contain nitrites and it is stated that this "undoubtedly accounts for its direct action in the reduction of blood pressure." Witter Water is also claimed to contain sufficient iodide to produce beneficial action. According to an analysis, the amount of sodium nitrite present in Witter Water is one and one-half grains per gallon, and for \$30 the sufferer from high blood pressure would get approximately ten grains of sodium nitrite. According to the analysis there is seven one-hundredths of a grain of potassium iodide in each gallon of Witter Water. Thirty dollars' worth of Witter Water contains less than one-half grain of potassium iodide. Yet the exploiters seem to think that the sodium nitrite content and the potassium iodide content are something to talk about (Journal A. M. A., June 27, 1925).

ACUTE PANCREATITIS

By CLARENCE G. TOLAND, M. D., *Los Angeles*

Acute pancreatitis can be conveniently divided into three types: acute interstitial pancreatitis; acute suppurative pancreatitis; acute hemorrhagic pancreatitis—pancreatic necrosis or gangrenous pancreatitis.

The consensus of opinion seems to be that the cause of the acute interstitial form is extension of infection through the lymphatics from an acute inflammation in some neighboring organ, such as the gall-bladder, the appendix, or a duodenal ulcer.

Acute hemorrhagic pancreatitis is generally considered to be a distinct disease and is thought rarely to be infectious in origin.

The diagnosis of acute pancreatitis in any stage is very difficult.

We must differentiate between this acute disease and incarcerated epigastric hernia; acute gastric dilation; ptomain or mineral poisoning; angina pectoris; spasm of the mesenteric arteries; mesenteric thrombosis; ruptured aneurysm of the abdominal aorta; acute intestinal obstruction; acute hemogenous infection of the left kidney; perforation of undescended retrocolic appendix; ruptured ectopic pregnancy and Pott's disease.

DISCUSSION by Dexter N. Richards, Oakland; A. R. Kilgore, San Francisco; William Henry Gilbert, Los Angeles; Herbert A. Johnston, Anaheim; E. T. Rulison, Sacramento.

THE most serious of the acute abdominal diseases with which we, the surgeons, have to deal is acute pancreatitis. The symptoms are acute, the diagnosis is obscure, the treatment is radical, and the results are not satisfactory, many cases terminating fatally—about 60 per cent.

No one has been able to definitely prove the exact cause of acute pancreatitis, and as a result there has appeared a large mass of experimental work and speculation on the subject. A number of men have produced acute hemorrhagic pancreatitis by injecting various substances, such as bile or duodenal contents into the pancreatic ducts, while others have worked out a lymphatic connection between the pancreas and appendix and gall-bladder. They have shown that infection could extend from an acute process in either of these organs through the retroperitoneal spaces to the pancreas. The pancreas is subject to the usual inflammations affecting parenchymatous organs, but it is unique in being affected by a special inflammation due to a chemical action or an enzymic activity. Therefore, acute pancreatitis can be conveniently divided into three types: acute interstitial pancreatitis; acute suppurative pancreatitis; acute hemorrhagic pancreatitis—pancreatic necrosis or gangrenous pancreatitis.

Unless the condition is marked, producing a large pancreas, acute interstitial pancreatitis is often not recognized. Not infrequently it progresses to suppuration with localized abscess formation—the acute suppurative pancreatitis. "In some cases of acute hemorrhagic pancreatitis the hemorrhage remains localized; in others it bursts through the serous covering into the lesser or greater sac, producing what is known as 'perforation of the pancreas.' In this stage fat necrosis is found." "In cases where the hemorrhage remains in the peritoneal capsule of the pancreas, secondary infection occurs later, producing a pancreatic abscess."

The consensus of opinion seems to be that the

cause of the acute interstitial form is extension of infection through the lymphatics from an acute inflammation in some neighboring organ such as the gall-bladder, the appendix, or a duodenal ulcer. A lymphangitis of the interstitial portion of the pancreas results.

Acute hemorrhagic pancreatitis is generally considered to be a distinct disease and is thought rarely to be infectious in origin. The common cause is a retrojection of abnormal bile; that is, bile rich in salts, into the duct of Wirsung or to a retrojection of duodenal contents into the duct of Santorini. Either of these agents in the pancreatic ducts activates the proteolytic ferment, trypsin, resulting in digestion and necrosis of the parenchymatous cells, erosion of blood vessels, and hemorrhage.

In a recent study of 100 necropsies, Cameron and Noble have produced an obstruction in the common bile-duct by the lodging of a biliary calculus in the ampula of Vater. In 65 per cent of the specimens studied, they demonstrated that the biliary and pancreatic ducts were converted into a common and freely communicating system and proved the possibility of a reflex of bile up into the pancreas.

Woring of London believes that all cases of acute pancreatitis are due to infection, and the bacillus coli communis is nearly always the infecting organism; occasionally streptococci may be found. He believes, through the study of fifteen cases, there is little doubt that the primary source of infection is generally the gall-bladder or the duodenum. The infection is spread from these organs to the pancreas by the lymph vessels or by the pancreatic or common bile-ducts. We feel that in the majority of cases this is true.

Fat necrosis is present in all cases of acute pancreatitis except in the acute interstitial type. It is thought by most of the medical profession that fat necrosis is due entirely to the local action of pancreatic juice; but cases are on record in which the process has been found both in the pericardial and extrapleural fat, leading one to believe that fat necrosis may be attributed to ferments liberated by the diseased pancreas and circulating in the blood.

SYMPTOMS

The symptoms of acute pancreatitis may, for convenience, be tabulated as to Woring—pain, vomiting, rigidity of the abdominal wall, rise of temperature and pulse, cyanosis and jaundice, localized abdominal swelling, diastase in the urine and glycosuria.

The pain is usually very sudden, located in the epigastrium or left upper abdomen and in the left lumbar region, often radiating to the left shoulder, left flank and anterior lower chest. It is usually so severe and sudden as to cause immediate collapse. In Case 2 the patient was so shocked it was feared she would die immediately.

Vomiting occurred in all of our cases immediately, the vomitus containing the stomach contents and bile; nausea persisted throughout the attack until the operation was performed or, as in Case 2, the stomach distress continued until death.

Rigidity of the abdominal wall was noted in three of our patients during the first twelve hours except in Case 3, where it lasted for four days; finally the

rigidity disappeared except in the upper abdomen and on the left side near the left costal margin.

Temperature at first is subnormal, the pulse is rapid and thready during the first five hours, becoming fuller as the temperature rises.

Cyanosis is very marked, especially of the extremities and face; this, to our minds, associated with sudden pain as described above, is almost pathognomonic of acute pancreatitis. We have never noticed jaundice; however, many writers say in the less acute cases a very slight icteric tinge of skin may be noted.

Localized Abdominal Swelling—It is occasionally noted that a distinct mass is felt in the upper left abdomen, extending across the spine to a few inches to the right; however, this is noted in only a few cases. We found it in Cases 1 and 3. In Case 3 a distinct rounded mass extended into the lesser peritoneal cavity; also it was distinctly outlined by x-ray examination.

Diastase in Urine—Normal urine contains 10 to 20 units of diastase. In disease of the pancreas, associated with pancreatic insufficiency, the diastase may amount to 100 to 200 units. Woring says that many cases of acute pancreatitis show this increase of diastase; but often in the very acute cases enough time has not always elapsed between the onset of the disease and examination of urine for this to be manifest.

Glycosuria—The cases are often so acute and need such immediate attention surgically, that enough time has not elapsed between the occurrence of the symptoms and time of treatment for sugar to show in the urine. We found no sugar in any of our cases. However, Case 3, which we still have under observation and treatment, only this week showed 138 mgms. to 100 cc. of blood, showing a slight increase above normal.

DIAGNOSIS

The diagnosis of acute pancreatitis in any stage is very difficult. The most important thing to keep in mind is the onset of the pain, its character and localization, associated with a cyanosis of extremities and face; the increase of diastase in urine; occasionally glycosuria and a slight icteric tinge of the skin; however, many cases occur in which the signs and symptoms are not sufficiently pronounced at first or their character has been so obliterated by giving morphine, that a correct diagnosis could not be made except by exploratory operation.

We must differentiate between this acute disease and incarcerated epigastric hernia; acute gastric dilatation; ptomain or mineral poisoning; angina pectoris; spasm of the mesenteric arteries; mesenteric thrombosis; ruptured aneurysm of the abdominal aorta; acute intestinal obstruction; acute hematogenous infection of the left kidney; perforation of undescended retrocolic appendix; ruptured ectopic pregnancy; and Pott's disease.

Cases 1 and 4 belong to the group classified as acute interstitial pancreatitis. Case 1, secondary to acute appendicitis, Case 4 followed acute cholecystitis with stones.

Case 2, that of a woman 38, belongs to the type of acute hemorrhagic pancreatitis. No operation was

performed because patient was too sick to attempt surgery, as far as we believed.

Case 3, a woman 41, belongs to the type of acute suppurative pancreatitis developing following acute cholecystitis with stones.

TREATMENT

The treatment of acute pancreatitis is always surgical, if the patient is not in extremis. Usually the sooner operation can be performed after the onset of the affection, the greater are the chances for recovery.

The greater sac of the peritoneum is opened and exploration immediately made. The pancreas usually feels rather soft; at times the color is cherry-red, again very pale. There is usually present in the abdomen a beef-broth fluid and fat necrosis.

After the pancreas is exposed, free incisions should be made into the swollen gland, usually parallel to the long axis of the organ. Drainage tubes are inserted down to the incised areas and the wound closed in the usual manner.

Case 1—Male, age 14, school boy. Referred to us March, 1922. Acute interstitial pancreatitis.

Present Illness—Following an attack of influenza, developed an acute perforative appendicitis with abscess formation. He was operated upon, the appendix removed, and the abscess drained. Aside from a troublesome cough, he made good progress and on the sixth day his temperature was normal. The next day the temperature began to rise and he noticed soreness in the upper right abdomen; the soreness gradually increased, and he soon developed a tender mass in this region. This mass steadily increased and resisted treatment, such as local hot applications. The thirteenth day the temperature was 104, and the pulse rapid and weak. Operation for a secondary collection, sub-hepatic or retrocaecal abscess, was decided upon. The laboratory tests showed normal urine; Hb. 70; R. B. C. 4,500,000; W. B. C. 20,000; and 90 per cent polys.

Operation—An incision was made to the outer right edge of the mass and a greatly enlarged pancreas was exposed. The pancreas was hard and tense and did not fluctuate. The capsule of the gland was incised to relieve the tension, and drainage tubes were inserted. There was immediate improvement in the boy's condition—his convalescence was smooth and rapid and in one week he was able to return home. At present, two years later, his condition is excellent.

Case 2—Female, age 38, housewife. Consulted us July 15, 1923. Acute hemorrhagic pancreatitis.

Present Illness—For about ten years has had attacks of what patient termed "stomach trouble," causing vomiting and occasional pain in the epigastrium. Six weeks previously, after eating an apricot, developed sudden acute pain which radiated over the whole abdomen; she vomited profusely and became distended. The symptoms persisted, and for five days there was no bowel movement. A doctor was called and an opiate given to relieve the pain. A profuse diarrhea developed which was very offensive. Her symptoms persisted unchanged for five weeks, at which time we first saw her. There was extreme emaciation; she was sweating and her limbs were cold; the abdomen was distended; had almost constant bowel movement; moderate tenderness in upper left abdomen and left flank. The pain radiated to the left shoulder and back. *Past History*—Operation for appendicitis, eighteen years ago. *Physical Examination*—Anemic, emaciated female in state of marked shock. Blood pressure, 120/70. Temperature, 101. Pulse, 140. Eyes showed dilated pupils. Considerable tenderness of posterior neck muscles with some rigidity. Rapid respiration. Lungs clear. Heart showed poor muscle tone.

Abdomen—Marked general distension from gas. Tenderness in epigastrium. No rigidity; no masses. Patient was sent to hospital. Laboratory tests showed negative *Widal*.

A diagnosis of diffuse peritonitis and acute pancreatitis

was made, but patient was too ill for operation. She was treated as a peritonitis case and improved somewhat. Continued to have frequent bowel movements with some blood; odor very offensive. On the fifth day she developed a profuse hemorrhage from the bowels and died four hours later, apparently from hemorrhage.

Autopsy showed an unusual condition. On opening the abdomen, the typical beef-broth fluid of acute pancreatitis was noted. There was fat necrosis everywhere; all the abdominal organs were acutely congested. No stones noted in gall-bladder nor common duct. There was a large retroperitoneal collection of blood and pus containing the pancreas free in the cavity. The lower left portion of the collection had formed a communication with the descending colon, and the colon was filled with blood and pus—Nature's attempt to evacuate the collection. Grossly and microscopically, the pancreas showed diffuse necrosis.

The autopsy diagnosis was acute hemorrhagic pancreatitis.

Case 3—Female, age 41. Referred to us September 10, 1923.

Present Illness—Well until ten years ago when she had a sudden attack of severe pain in the epigastrium; lasted about twenty-four hours and was associated with vomiting. Similar attacks two years ago and another six months ago; the latter required a hypo for relief. The last attack came on three days ago without apparent cause. There was sharp, cutting pain in the epigastrium followed by upper abdominal cramps. Took a saline purge, which was followed by vomiting, pain increased and required a hypo for relief. The acute pain recurred and has appeared at intervals up to the present. Marked tenderness in upper abdomen between attacks. The pain radiates to the right shoulder. Associated symptoms are meteorism, vomiting, chills, fever, and constipation. Patient feels very weak and ill.

Past History—Diseases of childhood. Malaria at 12. Menstrual history normal. Physical Examination. Anemic-looking female in state of moderate shock. Blood pressure, 120/50. Temperature, 101.3. Pulse, 98. Head, neck, heart, and lungs normal. Abdomen shows a tender mass in the epigastrium about the size of an orange; it is not movable; it pulsates and fluctuates on palpation. No bruit heard. Moderate rectus rigidity. Mass does not move with respiration and is dull to percussion.

Patient was hospitalized and treated by applying ice to epigastrium. Her condition improved for a week and remained stationary, when operation was decided upon.

Laboratory tests showed normal urine; negative Wassermann. Hb. 75; R. B. C. 5,000,000; W. B. C. 12,000; and 86 per cent polys.

Fluoroscopic by Dr. Granger—Tumor mass in the position of the pancreas, about the lesser curvature of the stomach and behind it, displaces stomach a little; not connected with stomach or intestines; may be inflammatory mass in the lesser peritoneal sac.

Operation disclosed an acute cholecystitis with distended gall-bladder containing many small stones. The pancreas was about three times its normal size, was hard and tense. There was an abscess in the midportion which extended into the lesser peritoneal cavity, and was attached to the posterior wall of the stomach. The abscess was exposed through the gastro-hepatic omentum, its wall sutured to the parietal peritoneum, and it was then opened. Drainage was maintained by iodoform gauze surrounded by gutta percha tissue. A cholecystostomy was then performed.

The convalescence was stormy, with chills and temperature up to 103. It was noticeable that her condition was worse when the gall-bladder did not drain and that she improved when the bile drainage was re-established. The symptoms gradually subsided, and in about four weeks she went home with a small opening in the upper angle of the wound discharging a clear serous, slightly irritating fluid.

At the end of three months the sinus closed. There followed immediately a distinct painful mass in the epigastrium. The mass was very tender and the patient, a nurse, was not able to follow her usual work. Several times the old sinus opened spontaneously, giving sudden and complete relief from pain; tenderness and the tumor

disappeared completely. The sinus, however, would close again and immediately the former symptoms would return.

Five months after operation patient was re-operated for a tender mass in the pancreatic region. The former sinus had closed and could not be opened. The pre-operative diagnosis was "pancreatic cyst."

At operation a cyst was discovered, evidently involving the body of the pancreas. The cyst was about the size of an orange and contained clear fluid. Because of dense adhesions and its intimate relations with the pancreas, the cyst could not be removed.

The cyst was opened, the cut edges sutured to the edges of the abdominal incision, and the cyst cavity lightly packed with gauze.

Convalescence was uneventful, and patient went home in four days. She obtained complete relief from pain and at present is able to do her work as nurse, and has regained normal weight and strength. There is still a small packing of gauze in the wound and considerable watery drainage.

Case 4—Female, age 35. **Present Illness—**Three years ago patient complained for the first time of sharp pain in right upper quadrant which remained localized for a few hours. She had some nausea, but did not vomit; was feverish and had poor appetite. On November 30, 1923, patient had a similar attack; pain did not radiate, but remained localized in epigastrium. There was vomiting and considerable nausea. Between attacks of sharp pain the patient felt a distress in the epigastric region. There was no jaundice. Patient stated she had never been sick, but her bowels had been constipated for many years, and her appetite poor. Family history showed no tuberculosis, cancer, insanity, nor diabetes. **Physical Examination—**No abnormalities except moderate upper abdominal rigidity with marked tenderness; no mass.

Pre-operative Diagnosis—Perforated du. or subacute cholecystitis.

Operation—On December 1, cholecystectomy for acute cholecystitis was performed, and showed the gall-bladder about four times normal size, very white, great deal of edema. Marked edema of the mesentery of the transverse colon and omentum. Marked amount of beef-broth fluid in the abdominal cavity. Pancreas about twice normal size, but extremely soft. Exploration of stomach, appendix and spleen negative. A small cyst size of hen's egg right ovary, which ruptured on examination. Marked deformity of the cystic duct to the common duct—runs parallel with the common duct for about one and one-half inches.

Microscopic findings were subacute cholecystitis, multiple mixed gall-stones.

Recovery was uneventful. Profuse bile drainage at first with considerable abdominal pain, but each day showed less drainage and less pain.

Patient left the hospital December 19, wound clean and patient feeling well.

On March 1, patient returned for examination. She was apparently in good health, and there was no drainage from the wound.

Pacific Mutual Building.

DISCUSSION

DEXTER N. RICHARDS, M. D. (Medical Building, Oakland, Calif.)—My personal experience with acute pancreatitis has been limited and the correct pre-operative diagnosis has been rare. I would mention in the list of diseases to be differentiated from it, acute perforation of gastric or duodenal ulcers. The suddenness of onset, the severity of the symptoms leave little doubt that there has been an upper abdominal catastrophe.

Personal history aids in a differentiation, and the physical signs not characteristic of perforated ulcer or other acute diseases mentioned by Toland, leads one by exclusion to a diagnosis of acute pancreatitis—sometimes.

Immediate operation, exploration, is always indicated. Convalescence is often protracted and may end fatally after recovery seems to be in sight.

A. R. KILGORE, M. D. (391 Sutter Street, San Francisco)—One fact stands out from Toland's paper and from the reading of other articles stimulated by it—sudden, agonizing pain in the upper abdomen, accompanied by signs of

collapse, ought to make the abdominal surgeon put acute pancreatitis high in his list of differential diagnoses. Accompanied by persistent vomiting, absence of fever, and the presence of epigastric prominence, the indications are sufficiently definite to warrant examination of the pancreas first in exploratory operation.

It is equally clear that early operation is indicated. Balch and Smith reported eleven operated cases with three recoveries, and ten unoperated cases with one recovery. Several of their operated cases were not explored until from two to three days after onset, and one cannot help but feel that a 70 per cent mortality might have been reduced by earlier interference.

The operative procedure of multiple longitudinal incisions in the gland capsule and drainage through the lesser cavity and gastro-hepatic omentum seems well founded and standardized.

WILLIAM H. GILBERT, M. D. (Brockman Building, Los Angeles)—I am satisfied that inflammatory conditions of the pancreas—more or less acute—exist with greater frequency than we suspect. It is not unusual for "stomach trouble" to manifest itself for which we can find no definite cause, the attacks coming and going with irregular frequency. Pressure in the upper left abdominal quadrant will many times elicit pain in these cases, and they may be a low-grade type of pancreatitis. As a consequence, the pancreas, as well as the gall-bladder and appendix, is coming into its own as a causative factor in obscure stomach derangements.

Toland's paper in a masterly way calls to our attention that particular brand of acute pancreatitis which belongs among the explosive type of acute abdominal conditions and requires boldness and prompt surgical skill in handling.

Violent pain in the epigastrium radiating upward and to the left, with Arthur Bevan's "wooden belly" accompanied by a highly resistant left costal arch, persistent vomiting, and pronounced signs of shock with cyanosis of the extremities, are the cardinal symptoms (if there be any) of this condition. It is indeed a question calling for rare surgical judgment and diagnostic acumen as to the advisability of operation with these conditions confronting one. That this is a surgical abdomen, goes without question. My own experience in two of these cases leads me to believe that surgical intervention offers the only rational method of procedure, and that it should be resorted to as soon as the physical condition warrants. The sooner the better, consistent with the well-established principle of non-surgical intervention, when shock is existent. On the other hand, unwarranted procrastination can only add to the already high mortality.

The procedure of multiple longitudinal incisions in the pancreatic capsule, accompanied by drainage, is the operation of choice, and I believe it to be the only method that holds out hope of lowering the high death rate that goes with these cases.

HERBERT A. JOHNSTON, M. D. (Clinic Building, Anaheim, Calif.)—During the last quarter of a century, diseases of the pancreas have received sufficient study that now the so-called "drama" of acute pancreatic disease is recognizable. It has been largely through the study of this organ, permitted by the surgical work performed on the gall-bladder, that its acute pathological processes are better understood.

Dr. Toland, in his estimable paper, emphasizes the importance of early diagnosis, though usually difficult. The sudden onset of upper abdominal pain, cyanosis of lips with pallor of face, and a tender mass in the pancreatic area are highly suggestive. A recent case operated upon here presented the following: Sudden, deep-seated, pain just above the umbilicus in a woman 24 years of age, six weeks after a normal delivery, and three weeks after an attack of mumps, the upper abdomen slightly rigid, and a diffuse tender mass palpable in the pancreatic region, marked cyanosis of lips, anxious expression and restlessness. At operation, twenty hours from onset, we found very marked fat necrosis, and more than a quart of the characteristic fluid in the peritoneal cavity. The pancreas was much enlarged and of a gray color. Tissues of the gall-bladder region were engorged and edematous. Multiple longitudinal incisions in the pancreas, and very lib-

eral use of rubber drains relieved the acute condition. The patient's life was in the balance for weeks. The secretion of fluid seemed to be almost unlimited, and the condition of the skin, surrounding the incision, became unbearable. After ten weeks in the hospital, the patient was discharged in a very weak and emaciated state, but at present is improving and will recover.

E. T. RULISON, M. D. (California State Life Building, Sacramento, Calif.)—Dr. Toland states "cyanosis is very marked, especially of the extremities and face; this, to our minds, associated with sudden pain as described above, is almost pathognomonic of the acute pancreatitis."

Cyanosis must be due to sub-oxygenation caused by the spastic fixation of the muscles of respiration. That this important sign may be associated with acute epigastric pain and a board-like rigidity of the abdomen in a condition other than acute pancreatitis is illustrated by the following case:

In August of this year I saw, at the Sutter Hospital, a man who had just been admitted with a diagnosis of perforated duodenal ulcer. The patient was prostrated, distinctly cyanosed, skin moist, suffering excruciating pain in the epigastrium and left flank, abdomen of board-like rigidity; temperature subnormal, pulse 84; vomiting of the stomach contents had occurred. In other words, the patient presented the picture Toland has so clearly drawn of acute pancreatitis.

Careful questioning of the patient, however, brought out the following: At the time of the onset he had been seated in an outdoor toilet; the initial transitory pain had been in the glans penis, but an instant later was felt in epigastrium and left flank, where it persisted. Examination of the glans revealed a tiny lesion which about three hours later developed a transitory urticarial wheal. Cyanosis and abdominal rigidity disappeared after forty-eight hours, and pains shifted to extremities and slowly decreased in severity.

The condition was due to the bite of the most venomous of our American spiders, *latrodectus mactans*. Kobert has isolated a toxalbumen from this species which, if introduced directly into the blood stream, as no doubt occurred in the case cited, produces symptoms and signs which simulate closely an acute abdominal lesion. Death has been known to ensue.

The Treatment of Diabetes Mellitus in Children—While many adult diabetic patients can get along without insulin, A. Graeme Mitchell, Cincinnati (Journal A. M. A.), says that practically all diabetic children will be benefited by its use, the severity and progressive character of the disease in them making it difficult to give a diet that will keep them sugar and ketone-free while supplying enough food for growth and development. The diabetic diet for children should be planned with three definite factors in mind: (a) The protein content; (b) the relation between ketogenic and anti-ketogenic substances, and (c) the glucose tolerance of the patient. It may be assumed that a child will require at least 1 gm. of protein for each pound of body weight. Protein-containing foodstuffs are selected that will furnish this amount. Ketogenic food substances must be balanced against anti-ketogenic food substances. If the diet contains not more than 2.5 gm. of fat for each gram of carbohydrate plus each gram of protein, ketosis will not occur. In continuing the planning of the diet in which protein has already been supplied in the proportion of 1 gm. per pound of body weight, the remainder of the food must be added so that there is 1 gm. of carbohydrate and not more than 2.5 gm. of fat for each pound of body weight. Children are especially prone to the development of acidosis, and it is well to keep the fat lower than would be permissible in adults, not much more than 2 gm. of fat being allowed per pound of body weight. This is particularly important in initial diets until the glucose burning power of the body is known. Mitchell gives details for the treatment of uncomplicated cases—cases in which there is diacetic acid in the urine and cases in which severe acidosis and threatening coma are present. Children must be under close surveillance lest they supplement their restricted carbohydrate allowance in a surreptitious manner.

EDITORIALS

PRESIDENT MACGOWAN'S ADDRESS

Our much honored and beloved retiring president, Granville MacGowan, crystallizes the ripe experience and the meditations of a mature and remarkably acute mind in his presidential address published on page 833 of this issue. Doctor MacGowan raises a number of problems that every doctor has thought about and he gives us the benefit of his experience and judgment in the solution of some of them.

One of the most hopeful signs in our many-sided medical progress is, that more and more physicians are becoming actively interested in the broader, and probably the more important, problems of physicians as classified usually under medical economics, ethics, medical politics, and public health. All physicians admit that one of our greatest failings in the past consisted in devoting our talents too exclusively to bedside interest in sick people, thereby overlooking the necessity for carefully planned and homogeneous mass action in solving some of the broader problems that reflect upon communities as a whole and by which physicians en masse are more likely to be judged than by the striking individual successes of individual physicians in the care of individual patients.

"COLD SCIENCE, EFFECTIVE BUT NOT ALWAYS CONVINCING, has come into nursing and medicine, as sentiment has been squeezed out. It has been remarked that in the beginning medicine was all art and no science, while now we are trying to make it all science and no art."

There is a whole essay in the above epigram quoted from Edward N. Ewer's inaugural address as president of the California Medical Association (page 838). It was difficult to select this outstanding quotation from this unusually able and thoughtful address, every sentence of which has had the care and attention that makes literature—and authors. Our new president has something to say, and he says it in a way that makes light work for an editor and easy and profitable reading. His wholesome message should—and no doubt will—have the thoughtful attention of physicians individually and of organized medicine.

A WARNING!

In calling the attention of doctors to the upgrade tendencies of poliomyelitis, the California State Board of Health Weekly Bulletin says:

"In the weekly bulletin for April 11, 1925, attention was called to the undue prevalence of poliomyelitis. It was pointed out in that issue that poliomyelitis is ordinarily more prevalent during the early fall than during any other season of the year. Attention was called to the fact that experience has shown that, in those years when more cases than usual appear during the spring months, pronounced outbreaks of quite extensive proportions nearly always occur during the fall of the year. Since the

publication of these statements last month, still more cases of poliomyelitis have appeared. About thirty cases have occurred in California during the past four weeks, as many as twelve and thirteen cases having been reported during separate seven-day periods."

"There has not been an extensive outbreak of poliomyelitis in California since 1915. *The present trend of the disease, however, indicates the necessity for providing every possible safeguard against an epidemic of the disease next fall.* Prompt reporting is essential, for this is the first and most important step in the control of this disease, and unless all suspected cases are reported and investigated without delay, the control of the disease is made extremely difficult."

The physician who is thoughtless or negligent assumes a responsibility that should cause him unhappiness—at least.

SOME PROBLEMS OF DOCTORS

"Dear Editor," writes one of our good doctors, "When you have time and opportunity, will you be so kind as to give us an editorial or other comment, telling us what is our duty, and what is our best policy in handling a certain type of case. This inquiry comes to mind as a result of two incidents that have happened to me; in order to make my request plain it will perhaps be best to relate these incidents in detail.

1. "Some months ago, I was asked by one of our leading men to see a case of diphtheria with a man who is a —, although he has a P. & S. license. This proved to be a case of laryngeal diphtheria in a child of 8 or 9 years who had been under treatment for four days. No antitoxin had been given. I used very straight talk to the parents and I was successful in my argument, so that they allowed me to give 60,000 units, in spite of their religious opposition. I did not see the child again, but was told that he recovered from the local symptoms of diphtheria, but died four days later of heart paralysis. THE ANTITOXIN WAS GIVEN THE ENTIRE BLAME FOR THE DEATH. As a result of this occurrence, I resolved that in the future I would not be quite so positive in my arguments, but would state the case and let the parents decide.

2. "A few days ago, I was called to see a boy of 9 years who had had diphtheria six days without treatment. The parents said they wanted me only to make a diagnosis, *that they would treat the case.* I told them they were letting the boy die from neglect, and left it to them to decide. They said they would call me up later if they changed their mind. The culture from the throat was positive; also a smear taken at the same time. So, without waiting for the culture, the matter was reported to the health officer, who placed a quarantine on the house. Two days later an undertaker called me over the phone and asked me to sign a death certificate in this case. I refused to do so.

"The other day, while discussing the above with some of the other doctors, I was rather severely criticized by a man for whose opinion I have great respect. He told me that I did not do my whole duty; that I should have taken the matter up with the coroner at the time, instead of with the health officer.

"Since death resulted in each of these two cases, the matter is serious. If it were a matter of adults who were refusing treatment for themselves, I should not worry much, but as it was a child in both cases, I do not feel comfortable if I have not done all that was possible.

"I would appreciate, and perhaps others might also appreciate, a statement from you as to what one should do in such cases. If one urges the use of antitoxin and is successful in his argument, one is blamed for a death

if one occurs; if one urges the use of antitoxin and does not carry his point, he is guilty of neglect in the view of his confreres.

"Does the coroner, or any other officer, have the power to compel treatment of children in such cases?"

COMMENT

One of the oldest of known epigrams is to the effect that one cannot work in a stable without carrying the odor of manure. It is equally true that an educated ethical physician cannot consult with nor connubiate with a cultist—licensed or unlicensed—without attaching to himself the odor of cultism. Unquestionably, our correspondent, whom we personally know to be a competent physician of the highest integrity, made his first mistake in "seeing his patient" *with an inadequately educated "doctor."* It is true that too many otherwise educated, useful and often older physicians, some of them high in popular esteem, furnish examples of such unethical conduct in their relation with cultists. But all such men are either unbelievably stupid or mercenary beyond hope. Stupid, because no matter how deeply they think they have buried their heads in the sand, they fail to appreciate that their weird odors travel further and faster among their colleagues than do their virtues, be these ever so numerous and valuable. See your patient, yes, by all means, but refuse to recognize or consult with any cultist or so-called "doctor," even though licensed, who will treat a diphtheria patient for four days without using antitoxin.

It is difficult, it is true, to see an irresponsible child going to almost certain death with diphtheria, without having the marked advantages that all physicians *know* accrue from the intelligent use of antitoxin. Nevertheless, our correspondent was perhaps overly insistent, in view of the peculiar religious and medical beliefs and practices of the parents. It is well in circumstances of this kind to insist upon the presence of some other safe intelligent witness and follow-up worker—*preferably a reliable nurse*. And once having assumed the proper responsibility of administering antitoxin to an obviously desperately sick child, the doctor should have followed this step up by frequent subsequent visits. *This should have been one of the stipulations made before the antitoxin was given.* It is not enough to throw a lifeline to a drowning person; the service must be followed up.

Our correspondent's conduct of the second case was above reproach. Having very properly refused service under the conditions imposed and having reported the matter to the official public health authority, his duty was fully discharged. It was the duty of the official health department, once in charge with their yellow card on the house, and not that of the doctor, to see that justice was served, including a report of the matter to the coroner, if they believed, as apparently they had reason to suspect, that someone ought to be prosecuted for manslaughter. Our correspondent does not tell us *who did* sign the death certificate.

The trick of asking doctors to sign troublesome death certificates to protect incompetent cultists, self-medicators, and those fortunately rare parents who want to treat their own children, whether by

prayer or pills, is an old one. Public health officials claim that too many doctors jeopardize their standing, and in several instances recently, their freedom, by acceding to such requests. Our correspondent expresses the universal sentiment of good doctors when he particularly deplores neglect, or worse, of sick children, but it is well to remember that the contractual relations between the personal health physician and his patient are private and, to a degree, privileged. Society has established and maintains public health services, courts and coroners to see that the interests of the state in the child are maintained, and to punish when necessary. It, of course, is the duty of the personal health physician to report such matters as he mentions to the public health authorities and it is wise to do so in writing, retaining a carbon copy of the letter. Of course, no harm is done and sometimes the cause of humanity is better served by also sending a copy to the coroner or district attorney.

No, doctor, neither the coroner, nor any other official or person, except the parents or guardian, has the authority to *compel* intelligent treatment of children in California, even though they may be strangling to death from a growing diphtheritic membrane as certainly as they would suffocate if thrown into a river. Courts in several other of our states have recently convicted meddlers, cultists and *in instances, even parents, of manslaughter*, under conditions not far removed from those you describe. There isn't much chance for such successful enforcement of law in many places in California at the present time.

The columns of CALIFORNIA AND WESTERN MEDICINE, and even those of a few newspapers, are open for the publication of FACTS such as you mention in the unpublished paragraph of your interesting letter. Let us have more questions of such vital importance from good doctors who are troubled in spirit. The editor will welcome additional comment upon the question raised in this letter and editorial, and will use, with or without mentioning names, such matter as appears useful to the cause we all espouse.

Are Modern Public Health Departments Becoming Great Organizations for the Practice of Medicine?

A growing number of writers, medical and non-medical, believe that many health departments are going far beyond their legitimate business. Doctor C. D. Selby, in his inaugural address as president of the Ohio Medical Association (Ohio Med. Jour.), sums the situation up in a state where the issues have been much discussed: "The 'modern health department' wishes to perform all kinds of medical service for the public, vaccinations, Schick tests, the Dick treatment of scarlet fever, the treatment of tuberculosis, etc. It is hardly necessary to say that this policy is fallacious. It is our duty as physicians and as a profession to bring health officers to understand that *every physician is a health officer*, and that these treatments which health officers are attempting to apply en masse are treatments that can much better be applied by individual physicians. The best health officers are those who secure the co-operation of physicians and persuade them to become individual health officers for their clientele."

Dr. O. Pine queries: "Why all this frenzied haste to embalm the 'family physician' before he is dead? Only his purse has been lacerated, not his usefulness!"—Atlantic Medical Journal.

The Month With The Editor

Notes, reflections, extracts from correspondence, comment upon medical and health news in both the scientific and public press, briefs of sorts from here, there and everywhere.

Curing Broken Legs by Prayer—The most audacious attempt of the unqualified to secure *legal* right to practice medicine, of which we are informed, was exemplified during the recent legislative session, when a well-organized attempt was made to allow "treaters by prayer" all the rights and privileges of educated licensed physicians.

Among other things, this proposed law was to grant "any employe" the right to select "treatment by prayer or spiritual means" in lieu of medical and surgical treatment.

And the "prayer" or spiritual "doctors" were to have full and complete authority in the preparation and signing of official documents upon which the consequences of injury, including compensation are based.

There is an interesting and more complete story of this and some other curious and significant measures which were before the last legislature, and what happened to them, and why, in the June issue of *Better Health* magazine. More of the story will be told from time to time.

"Why Patronize Your Family Doctor," asks one of our correspondents, "when our tax-supported public health authorities advertise to render important doctor's services *free* for you—regardless of your wealth—as they do in the following from the State Board of Health Weekly Bulletin: 'The Bureau of Child Hygiene of the California State Board of Health is sponsoring conferences in many counties throughout the state, where *pre-school children* may be brought for *free physical examinations*.'"

A "BEST SELLER"—A man went into Cohen's Book Store and asked: "Have you a copy of 'Who's Who and What's What,' by Jerome K. Jerome?"

Cohen replied: "No, sir; but we've got 'Who's He and What's He Got,' by Bradstreet."

MORE MESSAGES ABOUT THE HISTORICAL NUMBER

ON BEHALF OF THE SAN DIEGO COUNTY MEDICAL SOCIETY, permit me to express our sincere appreciation of and admiration for the splendid Journal which your untiring efforts have evolved and which is now known as California and Western Medicine.

At the recent meeting of the State Society in the Yosemite Valley it was with pleasure that we noted the commendations for the Journal which came from all sides and we feel that California has good reason to be proud of one of the foremost medical publications in the United States.

Very sincerely yours,

George B. Worthington, M. D., President.

"MY DEAR DR. AND TOO INDULGENT CRITIC," writes Doctor Adolph Barkan from Zurich, "may an octogenarian colleague be permitted to thank you for the few beautiful lines, and the sentiment expressed through them, which you have seen fit to put at the head of my sketchy remembrance of Macewen?"

When in the year 1869 I came to the Pacific Coast, in fulfillment of my boyhood's determination—to cure the blind and live in California—there appeared the Pacific Medical Journal in S. F., edited by that lovable man, Dr. Henry Gibbons, Sr. Will you put that alongside the historical number of California and Western Medicine? Let us—including myself into the ranks of the generation of medical men still young in spirit—be grateful for the progress achieved in our holy and beautiful profession, and under able leadership ever continue the good work. Again, my dear Dr., I thank you, and wish you well and many years more of progressive and encouraging work."

—THIS IS TO CONGRATULATE YOU AND THE AUTHORS on the very excellent articles which recently appeared on The Historical Number of California and Western Medicine. The articles were splendidly written and edited and made very interesting reading, in addition to being a change to many of us. I hope that in the future you may see fit to publish other similar articles.—J. Park Dougall, M. D., Los Angeles.

—ACCEPT MY CONGRATULATIONS on your interesting historical May number. Some of these pioneer physicians deserve our admiration for their courage and resourcefulness. Without the help of our modern laboratories some very good work was done.—Kaspar Pischel, San Francisco.

Preventing Babies—Doctor Pusey, ex-president of the A. M. A., in an address before the recent birth control conference, pointed out that legitimate practice in this field is a responsibility of physicians. "Doctors' methods," he said, "do not appeal to the mooning sentimentalists, or the so-called moralists, or to the ethical dreamers who would like to have mankind not as it is, but as their dreams would picture it."

—The 821 doctors who attended the convention passed this sensible resolution: "Resolved, That at this session of the Sixth International Neo-Malthusian and Birth Control Conference this meeting of American physicians affirms that birth control, being a very important and complicated problem requiring scientific study and guidance, comes properly within the province of preventive medicine, and that the subject should not only have a place in the programs of county and state societies and of the American Medical Association, but also becomes a part of the work of clinics, hospitals, and other medically supervised organizations engaged in scientific study and prevention of disease and crime."

THE 1926 A. M. A. session will be in Dallas, Texas. Let's begin to plan now and send at least 1000 California, 200 Utah, and 100 Nevada physicians to that convention.

Our New Trustee—Doctor Joseph A. Pettit, Portland, has been elected trustee of the American Medical Association to fill the unexpired term of Doctor W. T. Williamson of blessed memory.

Trusteeship of the American Medical Association for the West Coast section is a particularly important position, and we have every confidence that Doctor Pettit will represent us wisely.

Another Friend Honored—President-Elect Wendell C. Phillips of the American Medical Association is another of those "barefooted farmer boys" who have made good.

He plowed barefoot when he was so small, that the plow-handles would toss him in the air when the plow struck a rock.

—Did the hard work injure or benefit him? He believes the latter.

The Tonsil Crusaders—"Undoubtedly," believes the editor (Jour. Ind. Med. Assn.), "the pendulum has swung too far toward radicalism in the removal of tonsils to cure or relieve many diseases or symptoms of the human body, but this conclusion must be based on the knowledge that the worst offenders are the commercial operators who operate for the fee or the experience; or, on the other hand, by the class of physicians who are enthusiasts or faddists concerning a procedure that, while having its limitations, is considered to be beneficial in a large proportion of cases."

"When all is said and done, the point made by Barnes may be emphasized, and that is that the tonsils should never be removed without adequate cause, but when such cause exists the loss of a questionable functioning power should not be used as an argument against their complete extirpation."

—Certain clinics, health centers and groups of California health uplifters are still beating the bushes for children whose tonsils they want out on the say-so of technicians. *It takes a good a doctor to tell when a tonsil should come out as it does to take it out.*

Blood Money—Now that the Supreme Court of the United States has ruled that the Harrison Narcotic Law is *purely a revenue measure*, we find our country in an unenviable position, morally and socially speaking, in another of its tax practices.

Heretofore it has generally been denied by government officers that the law was primarily a revenue measure.

—It would look better to keep on being untruthful about it.

Balto!—The self-designated "Citizens' Medical Reference Bureau" is making itself again ridiculous in objecting to the proposed statue to the dog Balto because of his glorious run to Nome with life-saving antitoxin. *These people seem to think that Balto was a family doctor.*

Exercise, Work, Play—Queen Victoria never walked when she could ride, and exercise in general she avoided. She lived to a ripe old age. Walter Camp, who all his

life had kept himself in the "pink of condition," died much younger of cardio-vascular troubles. "What is one person's poison is another's food," is quite as true today as it was before we all became "educated."

Testimonial-Giving Again Becoming "Stylish"—When Chambers of Commerce made "leg shows" "stylish" and "theoretically respectable," they opened quite a "jack pot": they put a punch into the craving for publicity.

—Vanity looking about for its essential flattery discovered that the old custom of getting our names before the public by giving testimonials had been allowed to drift into obscurity, if not unrespectability.

—So, by reviving the custom and making it respectable by engaging the help of a few respectable people of prominence, a chance is provided to satisfy the publicity craving for another large group.

DR. STABEL MAKES THE STATEMENT (*Better Health*, June) that the successful country doctor requires more knowledge, experience and devotion than his city colleague. "The latter," says the doctor, "has specialists at his command to *divide* the responsibility which the country doctor has mostly to bear alone."

THE study of scientific medicine and the practice of it is a religion; it is a good deal nearer a religion than any other vocation on this earth. It ought to be kept far above the suspicion or the taint of commercialism.—Hubert Work.

Osteopaths "Educate" the Public—Some of the things said at the recent state convention of osteopaths that the newspaper men attached value to were:

"Professor Emery, widely known cancer expert," is credited with the startling statement that "The same influences that cause painful flat-foot, falling down of any of the organs, teeth-decay, and other breaking down of tissues, are the influences that cause cancer."

The old chestnut that cancer "is a disease of civilization" was polished up by Emery, who said: "It is not known among primitive people, nor was it known among the ancients—all of whom have the most perfect teeth, as I found in examining the skulls of the Egyptian mummies, those of the Peruvian Incas, those found in the catacombs at Rome, and in my world travels among primitive people."

There is plenty more of the same sort of misinformation about other subjects that some people no doubt will accept and act upon.

Oh Those Hollow Hairs!—"Progress of medical science, as developed by a New York barber and advertised by a sign in his shop, according to the *American Mercury*:

"After the hair is cut it should be singed in order to close up the ends. This prevents your catching cold in the head through the open ends of the hairs."

BOOTH TARKINGTON (*American Magazine*) makes the doctor say: "Why shouldn't we eat, drink and be merry, since tomorrow we die?" Well, the easiest answer is another question: But suppose you don't die? And the confirmation the world is seeking is confirmation of the ancient but shaken faith in that supposition. Man wants to know if there is eternal life and if there is God. If he finds an affirmative answer to either question, he'll accept it as the answer to both. If he finds that death is merely a change in continuous life, he'll know there is God. Isn't it curious that in the beginning man knew perfectly well that death was only a change in life, and not extinction of himself at all?"

There is much more in the essay by this delightful author that may be read with interest and profit.

It Is Said to Cure "Fear Complexes"—Mr. Samuel F. Rutter, Federal Prohibition Director, reports that Northern California residents legitimately consumed 1,200,000 pints of liquor in the twelve months ending May 1.

This represents the amount of spirits prescribed by physicians. There are 7300 physicians in California who

have the right to prescribe liquor, but proceedings are under way to revoke the licenses of forty-five of these.

California State Hospitals Establish Beauty Parlors for Patients—According to a recent news item from Sacramento, Mr. Walter D. Wagner, Director of State Government Hospitals, has established beauty parlors in state hospitals for their "wonderful psychological influence on the women inmates."

"The Tragedy of the Dirty Room"—Why tragedy instead of tragedies we don't know, but in any event **THE** tragedy is, that dirty rooms cause asthma, according to an amazing interview displayed in the press as being from one of our California doctors.

Your back aches because:

"Kidneys," said the herb man.

"Prostate," said the G. U. doctor.

"Flat-foot," said the shoe doctor.

"Pelvic trouble," said the gynecologist.

"Infected teeth," said the dentist.

"Mal-adjustment," said the osteopath.

"Impinged nerves," assured the chiropractor.

"It don't ache," emphasized the Christian Scientist.—*Medical Herald*.

FATE makes no free gifts; it sells, for a price. The price is heavy. Machine guns, cancer, slums, the penny newspaper—these are a few items of the tribute we pay to fate for the privilege of not being savages."—Aldous Huxley (*Vanity Fair*).

Our Sins Will Find Us Out—"The responsibility of diagnosing a healthy heart," says the *Medical Standard*, editorially, "should not be shirked because of the professional risk which the physician runs of giving a good prognosis in errors. . . . An attitude of playing for safety would be more justifiable if heart cases were doomed to end with the dramatic abruptness usually depicted by the novelist and imagined by the laity. . . .

"The tendency to excessive diagnosis of heart disease was rife during the war when thousands of men were rejected as unfit for service, or were invalidated out of the army, on the slenderest evidence of valvular disease and a mistaken notion of the ambit of cardiac manifestations. The morale of many ex-service men has been damaged to such an extent by this wrong diagnosis of heart disease that they will never again consider themselves fit for work. . . .

"Whatever the temptation to do otherwise, there is seldom any justification in the realm of heart trouble for other than a preliminary statement that either there is something wrong with the heart or there is not."

It takes a good doctor and an honest one to affirm that there is nothing important the matter with a given person's heart. It is much easier and safer for the unskilled to express a "strong suspicion," which is all the average patient needs to develop a first-class "fear complex." This most popular "fear complex" is surely being stimulated at present and, what is even worse, is being capitalized by people who are not adequately prepared in intelligence or experience to tell the difference between an emotional tachycardia and an arrhythmia. Ignorance, playing "safe," or cupidity explains an unknown amount of the "heart disease" statistics now so spectacularly featured.

An Unusually Intelligent Instrument:

"Dr. —, chiropractor, has equipped in his office a new nerve pressure register, which will register every degree of inflammation anywhere in the human body."

This is a copy of an advertisement clipped from a California newspaper and sent in by one of our members. We admit our inability to offer comment that would be understood by anyone who would fall for such bunk. We are informed that this chiropractor apparently is prospering, and in a community where at least the average amount of "health education" is passed around.

A Gruesome But Effective Health Measure—Scaring people into vaccination against smallpox by placing the sick, victims of this repulsive disease, near windows so that passersby may see them, is reported as proving an effective health measure in one place in New York. The health officer who introduced the innovation to help him overcome opposition to vaccination says: "During thirty-five years of continuous service as health officer here, I have never seen so marvelous a change in public sentiment on any such matter as occurred in the town referred to. Vaccination became, during the following week, a

popular pastime, and there are very few in this locality now who have not been vaccinated, although this happened twelve years ago."

THE docs do wrong when they protest against prohibition. No man should condemn an institution without first giving it a test.—Bugs Bear.

"Fake Prescription Forms"—So many counterfeit doctors' prescriptions for liquor are in circulation that the Internal Revenue Department has been obliged to issue an entirely new form, more difficult to duplicate.—*American Registered Pharmacist's Journal*.

66 **W**HAT a man does when he has nothing to do shows what he is."

Doctors are Citizens First—They are morally obligated to interest themselves in civic affairs and should be as active in promoting mental, moral and spiritual welfare as they are in promoting physical welfare.

"Short Turn Ahead"—That concern which is circularizing doctors and offering—for a price—to prepare and release articles to the public press under the doctor's name is finding some doctors who prefer notoriety to fame.

Who Said Fame!—Doctor W. E. Balsinger who, according to some newspapers, "gained international fame by transplanting one of Jack Dempsey's ears to where his nose should have been," was in San Francisco recently. He wanted an apology from Dr. George Warren Pierce, who has been quoted as saying that new noses built of paraffine won't last.

Does this confirm the old saying "that a prophet is not, etc."?

PROGRESSIVE INDUSTRIAL PHYSICIANS will find much to ponder over in Report No. 29, Industrial Fatigue Research Board of Great Britain.

The High Cost of Babies—Ida L. Allbright (Century) supplies food for thought in this well-told story of a "layman who acknowledges a large debt of affection and thankfulness to many men of the medical profession." Mrs. Allbright had her experiences with family doctors, specialists, groups, and clinics. Read her story, doctor; it may help you with your problems.

California Leads in Smallpox—Also in anti-vaccination propaganda. The two things go together. We led all the states during 1924 with 9425 cases of smallpox and fifty-six deaths. Ohio was our closest competitor, with 5597 cases and fifty-eight deaths.

Oh well, the anti's must spend some of their money, but why purchase a repulsive disease like smallpox with it? The pathetic feature of this *totally* (100 per cent) useless and unnecessary injury to health and sacrifice of life is, that many of the victims were children.

Deleting Babies—Extensive publication of the decreasing birth rate is now pointed to by some to prove how much more effective the modern birth control clinic is than was the old-fashioned doctor.

Mr. Ross, California's vital statistician, is quoted in the press as stating that: "Figures show that whether contraceptive methods are taught in clinics or not, their practice is general."

Mr. Ross also claims that: "The California average family of 2.68 persons is smaller than in any of the twenty-seven states that are in the registration area."

—Don't forget, Mr. Ross, that California must lead in "birth control," as well as in berries or anything else she attempts to do—or should I say not do.

Smith, being introduced to golf for the first time, had hit the ball a terrific whack, and sent it half a mile.

"Now, where do I run to?" he cried excitedly.

Are the Violet-Rays a "Nearly Cure-All"?—After reading that most remarkable, heavily headlined and illustrated interview with an M.D. from a Class A San Francisco Medical School the other day, we felt an inclination to turn over to the advertising "herbalists," "mental healers," and what not for some quiet reading.

Doctor, several of us are "over 40," our blood pressures

are higher than they should be, but we do hope you are wrong, at least, in your alleged statement that violet-rays "stimulate the growth of cells in the lining of the blood vessels."

When Is a Hospital Not a Hospital?—According to William C. Hassler, M. D., the official public health doctor of San Francisco, "*Christian Science Rest Homes*" are hospitals—at least from legal and public health viewpoints. The doctor elaborated his statement to say: "Unquestionably, this institution is a Christian Science hospital, but Christian Science does not recognize disease and so does not recognize hospitals as such and calls them rest homes."

—Nay, nay, holds Mr. McLeod of the Christian Science Publicity Department: "The statement that 'Christian Science does not recognize disease' is a complete misapprehension of its teaching and practice. In a relative sense, Christian Science recognizes disease as a mortal condition, to be rejected and destroyed *in accordance with God's law in the same manner as Jesus Christ destroyed it.*"

—This and other similarly significant statements from similar sources makes illuminating reading, particularly in connection with proposals to change the title of Christian Science practitioners to Doctors of Christian Science and with active attempts to give these people, BY LEGISLATION; all rights to treat patients under the Industrial Accident Law now included in physicians' licenses.

"That 'grand old man,' Dr. David Starr Jordan, has in no degree lost his sense of humor. His talk on 'Sciosophy' or the science of ignorance, was a scream."—San Diego County Medical Society Bulletin.

Why Some Leave Home:

"The city visitor was consulting the oldest inhabitant. 'How many people in this town now?' he asked.

'Twenty-five, sir.'

'How many did you have last year?'

'Twenty-five, sir.'

'That's strange, aren't there any babies ever born in this town?'

'Yes, sir. But most every time a baby is born, *somebody* leaves town.'

Birth controllers, take notice!

Catching Them Young—"Clinics for children of pre-school age which have previously been held at different homes will now be held in the association room *under the direction of the trained nurse and two assistants.*"

This quotation from an official tax-paid-for publication is representative of a type of quite familiar literature.

—A recent definition of a clinic is that it is a place where everyone but doctors practice medicine.

Playing Both Ends Against the Middle—According to a recent California Superior Court decision, chiropractors may now demand examination and license as drugless healers (if they pass) of the Board of Medical Examiners. Dr. Pinkham predicts that "there will be a rush of chiropractors to qualify under this ruling and he foresees great confusion arising from the dual jurisdiction. If a chiropractor holding licenses from both boards violates a medical regulation and has his license revoked by one, he can still operate under his license from the other."

—This dual convenience will provide many other kinds of *opportunities*. However, the outstanding fact is that even a drugless license from a board of educated physicians is more valuable to a chiropractor or other "doctor by law" than is the most attractive certificate that his own board can invent.

Another Fad Passing—Dr Matthias Nicoll, health commissioner of New York, has issued a warning against self-dosing with iodine. He points out that while this chemical may prevent goiter in children, it may also do harm to adults who have goiter already developed.

From numerous other reliable sources belated warnings are being issued against the indiscriminate use of iodine as a goiter preventive.

Iodine is a chemical and by no means a harmless one. Like other medicines, it should be prescribed by an educated physician when and where indicated, either for curative or disease preventive purposes.

—CALIFORNIA AND WESTERN MEDICINE has been preaching caution since the "iodine fad" first had its remarkable flare-up.

Medical Economics and Public Health

Both Timely and Important—The House of Delegates of the A. M. A. passed the following resolution at the seventy-sixth session:

"RESOLVED, That it is the sense of this House of Delegates that periodic health examinations should be conducted by medical men and neither dominated by nor controlled by lay organizations, for the reason that the relation between the patient and the physician is an individual matter, and anything that disturbs such relationship is detrimental to the best interests of the patient; and be it further

"RESOLVED, That it is the sense of this House of Delegates that every Fellow and member of the American Medical Association should live up to the spirit and letter of this resolution."

Health Officers Recently Appointed—According to the official bulletin of the California Board of Health, W. J. Quinn, M. D., of Eureka has been appointed health officer of Humboldt County to succeed F. R. Horel, M. D., of Arcata, who has held the office for many years. Doctor Quinn is licensed to practice medicine and surgery in California, and is a member of the California Medical Association.

J. W. Truxaw, M. D., has been appointed health officer of Anaheim, Orange County, to succeed George A. Paige, M. D. Doctor Truxaw is also a member of the California Medical Association.

Gilbert S. Bovard, M. D., has been appointed health officer of Sierra Madre, Los Angeles County, to succeed E. L. Jackson, M. D. Doctor Bovard is a member of the California Medical Association.

J. W. Camp, M. D., has received the appointment of health officer of La Habra, Orange County. Doctor Camp is a member of the California Medical Association.

Mr. M. B. Eaton has been appointed health officer of Sunnyvale, Santa Clara County, to succeed Mr. M. J. McGinnis. Mr. Eaton is not licensed to practice medicine and surgery in California, and is not a member of the California Medical Association.

The Physician and Narcotics—"The United States Supreme Court has just recently handed down an important decision dealing with the Harrison anti-narcotic law," says the Santa Cruz Sentinel, editorially. "The court holds," continues this editor, "that the law is strictly a revenue measure and must be so construed, interpreted and applied."

It also disposes of the more vexing problem, which has often been raised under that law, whether or not a physician may legally give small doses of morphine or cocaine to an addict under treatment.

"Dealing with this question, the court says: 'That a physician who in good faith dispenses small quantities of morphine or cocaine to an addict for the relief of conditions incidental to such addiction commits no offense within the Harrison anti-narcotic law.'

"Further on it says: 'The treatment of drug addicts and the wisdom or propriety of such treatment not being a matter for the determinates of Congress through the medium of a revenue measure.'

"The case upon which this decision was based was taken to the highest court of the land to test the powers of a physician under the law. That the court imposes the utmost trust in physicians in handling the dangerous drugs is shown by the fact that the decision does not even caution the physicians to exercise care, believing that under their oath when entering the profession they will do all in their power to aid an addict and will use wisdom and discretion in administering the treatment."

Another Health-Prolonging Group—A number of our members have sent in to us a most interesting document and return postcard on the stationery of a new "stay well," "positive health," "longer living," "college," "institute" association, or something of the sort. The idea of this new crowd is very much like the ideas of those that are now, and those more numerous ones that have been,

as well as some that are now and that won't be in the future. Their whole philosophy seems to be that because someone said (untruthfully) that the Chinese pay their doctors when they are well and require their services without pay when they are ill, the idea should be applied in America.

It probably would not be an exaggeration to state that the organizations that have attempted this and failed—at least for everyone except those who handled the money—would run into the hundreds.

The letter from this new organization which seems to have upset so many of our members shows on its face that it is prepared by people who have almost no fundamental conception of the problem they are undertaking. They fail to appreciate the difficulties that great governments have had in trying to apply this idealistic principle to everyday life. We anticipate that this latest of the many of these that are reported to us every year will not grow to sufficient magnitude to require any serious investigation and study by our departments that deal with problems of this character.

"'Modern medicine,' believes Doctor Sir David Bruce, 'must change its strategy in the battle against disease. It must begin the offensive and not await the attack.'"

Five Fundamental Standards for Ambulatory Patient Services—1. The outpatient and the bed services should be regarded as intimately associated phases of hospital work and should be unified as fully as possible as to medical staff and as to administrative organization.

2. The number of patients accepted for care should be limited and regulated according to the facilities of staff, space, and equipment.

3. Adequate records should be maintained of the medical work, the attendance, and the income and expenditure. All the medical records of a patient should be filed together.

4. Adequate laboratory service should be made available for the outpatient department.

5. Nursing service, social service and clerical service should be provided. Physicians should be able to devote their time to their patients and be freed from mechanical and clerical duties.—A. M. A. Bulletin.

Effective Sociology—"Are the passing of the old-fashioned hickory stick and the modern criminal wave related?" asks the Medical Standard, editorially. "So-called old-fashioned folks," cautions the editor, "think so, and take issue with the modern professors of psychology and sociology. Yet there is one modern professor who professes the beliefs of our fathers. To quote Dr. Rudolph M. Binder, of the sociology department of New York University, 'Spank 'em in moderation. Spanking is a nature physical cure for the tense nervous cause and reaction of misbehavior.' Which licenses dad to say, 'Accompany me to the wood-shed, Ernest, and we will review our lesson in sociology.'"

Babies Come High—"Day nurseries, convalescent homes, and fresh-air homes in New York City represent an estimated investment of over \$15,000,000," states the annual report of Association of Day Nurseries.

"The budget of the Bureau of Child Hygiene of the New York City Department of Health," continues the report, "amounts to about \$900,000 for salaries alone. A study made of the day nurseries shows that this particular type of agency is reaching not more than 9000 families in a year, and takes care of about 15,000 children as a maximum. The total cost of maintaining the day nurseries is about \$1,000,000 a year."

Making Charity a Business Trust—"And, really," says Harper's Magazine, "an overdevelopment of that great industry of raising money by drives and campaigns and organizations for purposes which the organizers and the drivers believe to be good may come—if it runs to excess—to be open to the same objection which concerns the diffusion of the funds of the taxpayers. It may take away from the givers whom it reaches the ability to give their own funds to objects they think about and care about. When these great ebullitions of money-raising go out of style, that will be one of the reasons for it. People will say: 'We would rather ourselves give to what we wish to help than give to you to give to what you wish to help.' That is where the drives are weak."

California Medical Association

EDWARD N. EWER, M. D., Oakland.....President
 W. T. McARTHUR, M. D.....President-Elect
 EMMA W. POPE, M. D., San Francisco.....
Secretary and Associate Editor for California

THE YOSEMITE SESSION

The fifty-fourth meeting of the California Medical Association held at Yosemite Valley was a success from the viewpoint of the program presented and from that of the attraction of the meeting place. The total registration was 839, almost twice that in 1922. Few hotels bring the membership closer together fraternally than does the Yosemite Lodge, where only members of the California Medical Association and their families gather during the annual meeting.

Oakland, the home of our president, Edward N. Ewer, has been chosen as the place of meeting for the 1926 session.

Data about the annual meeting in Yosemite held on May 18 to 21, inclusive, could not be published in the June issue, as CALIFORNIA AND WESTERN MEDICINE went to press on May 20, prior to the close of the annual session. In this issue, therefore, are published the speeches of the president, president-elect, a full account of the Bunnell Memorial exercises, and the transactions of the House of Delegates. Because of the volume of material submitted, it is deemed wise to hold the minutes of the Council for the August issue. Certain Council action, however, should be brought to the attention of the membership early.

Clinical Prizes—As published in the December issue of this Journal, three prizes were established by the Council in November, 1924, in the sums of \$100, \$75, and \$50. After further consideration, it was felt by the Council that the amounts were too small and, therefore, at its last meeting the Council rescinded its former action and established two prizes for \$150 each—one for a paper on original research, and one for a paper on a clinical subject, to be competed for by members of the California Medical Association only. The competition will be so arranged that announcement of the prize winners can be made at the 1926 annual session to be held in Oakland. As soon as the committee has been appointed and the rules and regulations governing the competition formulated, full publicity will be given through the columns of CALIFORNIA AND WESTERN MEDICINE.

Preservation of the History of the California Medical Association—For some time the Council has felt that it is desirable to have a permanent committee to compile and keep up to date a full history of the organization, membership, and transactions of the California Medical Association, as the files and records prior to 1907 are very incomplete. At the Yosemite session the chairman of the Council was authorized to appoint such a committee. This is a most important function of the Association and it is hoped that any members who have

information on the subject will volunteer to collaborate with this committee.

Ownership of X-ray Plates—As many inquiries are constantly being received at the state office from doctors and hospitals, the general counsel was instructed by the executive committee to submit a form that would prevent question arising in either the minds of the patient or the doctor, hospital, or laboratory as to the exact status of x-ray plates. In compliance therewith the general counsel submitted a memorandum which was adopted in principle by the Council with the recommendation that it be formulated definitely for publication to the membership.

Certification and Recognition of Delegates at Annual Sessions—Much confusion and debate has always arisen at the annual sessions of the House of Delegates owing to the lack of definite rulings and regulations regarding the certification and recognition of delegates and their alternates. After much deliberation and consideration the Council has referred the matter to the executive committee with the recommendation that the proper amendments to the Constitution and By-Laws be prepared for consideration at the 1926 annual session, and that such amendments be made in accordance with the rules and regulations of the A. M. A. This means that only those delegates and alternates who are duly elected and officially certified to by their county society at least seven days prior to an annual session will be entitled to a seat in the House of Delegates.

Because of the non-attendance of so many delegates, the Council feels that "no delegate absent without notification to his county secretary or the state office should be considered eligible for representation the following year," and will recommend that this question be considered by the House of Delegates at its 1926 session, and that action be taken by that body along the lines quoted above.

DEDICATION OF MEMORIAL PLAQUE TO LAFAYETTE HOUGHTON BUNNELL, M.D.

Exercises held by the California Medical Association near Bridal Veil Meadow, Yosemite Valley, California, Tuesday, May 19, 1925, at 10:30 a. m.

The day was perfect. A gay company had assembled and formed themselves into a semi-circle, sitting on the greensward in a charming glade on the bank of the Merced opening into Bridal Veil Meadow.

The ceremony opened with what might have been a formal military salute, so well timed were the reports of a series of blasts from the road work near by.

Emmet Rixford, M. D., of San Francisco presided.

DOCTOR RIXFORD—I wish to call your attention to the completeness of arrangements made by Mr. Lewis, Superintendent of the Park, though he seems as surprised as any of us at this opening of the exercises with a military salute, as it were. One might almost imagine an aeroplane dropping bombs in the Valley to heighten the contrast of conditions of today with the mode of operations employed against the Yosemite Indians in 1851.

We are gathered here in this spot of wondrous beauty, with El Capitan towering aloft across the Valley and Yosemite Falls visible in the distance, to dedicate a tablet to the honor and memory of Doctor Lafayette Houghton Bunnell. I will tell you more about him later.

This site was chosen after much debate and many miles of running, and I know that all present will agree that it is not only a most beautiful spot, but is also most appropriate for a monument to Dr. Bunnell. Three sites were

Bunnell Memorial Exercises, Yosemite, May 19, 1925

considered—a spot near the foot of El Capitan, whose grandeur is a major theme in Doctor Bunnell's book; a second near the Royal Arches and Indian Cave, where several of the incidents of the stay in the Valley of the Mariposa Battalion took place and which had the advan-

tage of being more accessible to the public; and third, this secluded, but lovely spot.

Bunnell was not *the* discoverer of the Valley, but merely a member of the Mariposa Battalion, a company of thirty or forty, the first white men to enter it. His real distinction

lies in the fact that he suggested the name Yosemite Valley, and this little knoll leading out to the river beside the Bridal Veil Meadow is, as nearly as can be determined, the exact site of the first camp in the Valley of the Mariposa Battalion, and it was here that the name was suggested by Doctor Bunnell and adopted.

There is much that is indefinite in Doctor Bunnell's book, but the statements are clear that the first camp of the battalion was near the foot of the trail beside a meadow where the horses were staked out to graze. The company had Indian guides familiar with the best camping places, and we know that this very spot was an old Indian camp site because of the six or seven holes in the flat rock yonder where the Indian women ground their acorns. The identification was made by Mr. Lewis after carefully studying Bunnell's description with reference to the local topography.

Now for a brief history of the plaque. A committee was appointed two years ago, on the suggestion of Doctor Howard A. Kelly of Baltimore, that the medical profession erect a suitable memorial to this pioneer physician. The design by Mr. Paul J. Fair of the National Forest Service is of a grizzly bear representing the spirit of the Valley, standing erect in surprise and perhaps mixed emotions, viewing the entrance into his domain of the Caduceus, emblematic of the medical profession. Mr. Fair modeled the plaque with suitable inscription in honor of Doctor Bunnell, and Mr. Fred Storey cast the plaque in bronze.

The design was approved by Mr. Stephen T. Mather, Director of the National Park Service, after it had been passed upon by Mr. Daniel R. Hull of Los Angeles, landscape architect, and permission was given for the California Medical Association to place such a memorial plaque on some boulder at a suitable site in the Valley.

The plaque is to be mounted in permanent fashion on the flat side of the great boulder next the river, six feet or so above the ground.

The president of the California Medical Association, Doctor Granville MacGowan of Los Angeles, will now make formal dedication of the plaque.

DR. MACGOWAN—Fellow-members of the California Medical Association: As a learned society we are gathered together here in this, one of earth's most impressive spots, which had it been within the ken of the ancient Greeks would well, instead of Olympus, have been chosen as the home of the gods. Here are, within the reach of the senses, all of the attributes of nature, which cultured man without the belief of a sole sublime ruler might well with reason worship. The echoes of the voices of the waters and winds continuously surround us; soothe the traveler and lull him into oblivion; the wondrous groves spread mystery; the towering cliffs of ice-ground granite portray the hidden powers of might and strength; the lush meadows carpeted with delicate and tender flowers springing out from the concealment of the rich growing grasses reveal the protecting and sustaining powers of our mother earth. And all this majesty which we so admire and view with reverence had been, until a little less than three-quarters of a century ago, entirely concealed from the knowledge of the men who for thousands of years alternately created and destroyed civilizations growing out of the mental needs and ambitions of the white race.

Until 1851 no pale face had set foot upon the Valley floor. It had for all this time, within the memory of aboriginal man, been the abiding place and inheritance of a tribe mean of spirit and base of blood which was the scourge of the neighboring Indians and the terror of the haciendas of the plains. They absorbed no Godlike spirit from their environment. So secure felt they in their mountain fastness that when the work of the white men seeking for gold along the Valley of the Merced, the traces of whose activities may yet be seen, approached too close to the Valley gates, their dissembling chief, old Teneiya, picketed their work like a modern walking delegate and drove off the laboring force of Mission Indians who feared the Grizzlies, raided the stock, and refused parley with the commissioners of the government of the United States and defiantly brought about a state of war. It was then that the volunteer battalion formed in and about Mariposa, commanded by Major Savage, an Indian trader and commissioned by the then Governor of Cali-

fornia—MacDougal—was authorized and instructed to pursue these Indians and bring them into camp. One of these volunteers was a young man of 29, Lafayette Houghton Bunnell, the son of a Detroit doctor, who had received a partial medical education and had served at the beginning of the Mexican War as a hospital steward and later as a doctor. Young Bunnell was in the great adventure in California to seek his fortune in the gold mines. He attached himself to the military expedition through worship of the grandeur of mountain scenery, and a laudable curiosity to become further acquainted with the immense cliff, El Capitan, that he had seen from the old Bear Valley trail on the Merced River, looming in the Sierras.

A time of storm and heavy snow was chosen by the astute commander to approach the Valley through the totally unknown byway of the Mariposa trail. The surprise to the Indians was complete, and the expedition entirely successful. That night at the campfire, Bunnell, who was a devout nature lover and believer in America and American things and of a lyric spirit, proposed to those volunteer soldiers to name the Valley and presented to them the old Indian name by which the outlaw tribe was known to their neighbors surrounding them—The Grizzlies, Yosemite, the Terrible Bandits, of whom all were in fear. He wanted a true local name for the wondrous geographical basin that they had discovered. It received its baptism by the unanimous viva voce vote of the conquerors.

Bunnell did not remain in California nor did he practice medicine here, but returned to his old home in La Crosse, Wisconsin, where he enlisted in the United States Army, and was appointed a hospital steward and served during the entire Civil War, being promoted to assistant surgeon, and when he mustered out in July, 1865, had a commission as a surgeon, having in the meantime obtained a diploma in 1864 from an ephemeral institution in his own town—the La Crosse Medical College; his matriculation and class courses in the School of Hard Knocks and Internship in Camp Necessity justified the degree.

Later in life (he died in 1903) he wrote a most interesting book upon "The Discovery of Yosemite and the Indian War of 1851," which I would recommend now for any of you who are interested in tales of Indian warfare to read, because it is wonderfully descriptive of the early days of California and portrays the character of the man.

The California Medical Association has desired to keep alive the memory of this gentle, inconspicuous but honorable brother, and for this purpose we are here in the heart of the great Sierras dedicating this plaque, commemorating Doctor Lafayette Houghton Bunnell.

As appropriate I ask you all to rise, raise your left hands, repeating after me the 11 o'clock toast of a great benevolent organization to which many of us belong and which bears the name of the noblest of the denizens of this valley at the time it was discovered, "Cervus Alsus," To our absent brother.

DOCTOR RIXFORD—Mr. W. B. Lewis, Superintendent of Yosemite National Park, has given the committee the fullest co-operation and invaluable assistance. Aside from his official position, Mr. Lewis has always taken great personal interest in Yosemite Valley, and is a friend and often a friend in need of those who would enjoy the scenery of this world's most beautiful valley. Mr. Lewis will speak as representative of the National Park Service.

MR. LEWIS—Ladies and Gentlemen: I saw my name on the program for an address. Please do not look for one; it is not my business. I would like, however, to make an observation or two, and extend to you a hearty greeting from the National Park Service and Yosemite National Park, and also to extend to the California Medical Association the appreciation of the Park Service for doing this thing.

I think it is great to perpetuate things of historical interest. The old-timers are fast passing away, and each day we lose something of the early history of the Valley. It is only now that we are picking up threads and marking old sites. I think it is a wonderful thing to mark this place as the first camp of the white race in the Valley.

In thinking of that expedition of the Mariposa Battalion into the Valley, one cannot but compare conditions with

those of the present. I was thinking yesterday, with the roads in bad condition as a result of recent storms, that many of you on your way to the Valley felt you were undergoing severe hardships and probably criticized the Government for not having spent more money on the roads and Mr. Ford for not having put in better upholstery, and couldn't but wonder what Bunnell and his party had to criticize for the conditions then found.

Out of a camp of forty or fifty men it seems only Bunnell had an appreciation of the Valley and its grandeur. The rest were more occupied with hard service and work, and the idea of pursuing and catching the Indian. Bunnell was the only one who took time to show appreciation for wonders of the Valley and to make notes, and in later years to write a very good book of the expedition.

I do not know if Dr. Bunnell was a surgeon or not, but I am inclined to believe he was. Surgeons get great enjoyment out of exploring around incisions, and Yosemite Valley might well be thought of as an incision in the body of Mother Earth, hence, it would seem that only a surgeon would get the enjoyment out of exploring its depths as did Bunnell.

As a result of his interest in and study of Yosemite Valley during the limited time he was here, the wonders of the Valley became known to the world, but it is doubtful if he even imagined that in the relatively short time that has elapsed since that time, it would come to be known as one of the major scenic attractions of the world visited annually by thousands of people from our own and every other country of the world.

The route of the Mariposa Battalion into and through the Valley can be quite clearly defined. Coming from what is now Wawona on the south fork of the Merced River, they entered the Valley by the old Indian trail leading down from Old Inspiration Point, arriving in the Valley and camping on this site on the night of March 21, 1851. The following morning they crossed the river just below here, at what is known now as Valley View, and ascended the north side of the Valley for some distance, probably as far as Indian Creek, where the party split and scouting parties were sent out, one going up as far as Mirror Lake, one to the top of Vernal Falls, and back down the south side of the Valley to the Cathedral Rocks. By prearrangement they met again near the mouth of Indian Canyon in the evening, and camped there for the night. The following day they returned to Wawona by the same route followed on their incoming march. When it is remembered that all this was done in three days in the month of March, when the entire country they covered was well blanketed with snow, we must not fail to give that group of mountaineers the credit due them. Only the hardiest of men, thoroughly inspired with a sense of duty, would undertake and complete in that limited time such a hazardous journey.

It is, therefore, right and proper that this site be of record, not only in appreciation of Bunnell, but as the most important historical spot in the Valley.

Again let me extend the greetings of the Park Service and its full appreciation of the efforts of the California Medical Association in establishing this memorial in honor of the discoverer of Yosemite Valley.

DOCTOR RIXFORD: It seemed to the committee that it would be most appropriate on this occasion to have set forth something of the history of early exploration in the Yosemite region and the origin of the name. None is so well versed in this matter as Mr. Francis P. Farquhar of San Francisco, who has gathered together a great mass of material on the history of man's coming into the Sierra. Mr. Farquhar will speak as a representative of the Sierra Club.

MR. FARQUHAR—Members of the Medical Profession and Friends of Yosemite: Doctor Rixford has asked me to give you something of the historical background in order to bring out more vividly the significance of the expedition of 1851, when Bunnell came to Yosemite Valley as a member of the first party of white men to set foot here.

It may seem strange that this remarkable spot was so long unknown, but it should be remembered that scenery was not a prime objective among the early visitors to California. Mountains were a barrier and not an attraction. The Spanish occupation was confined to the coast for many years, and, excepting for attempts to reach the

coast from the settlements in Mexico by way of the lower Colorado River, little was known of the interior of California. In 1776 Father Garces entered the San Joaquin Valley and visited many Indian rancherias along the river. He did not ascend into the mountains, however, although his visit did fix the name of Sierra Nevada upon its present location. Formerly it had been rather vaguely assigned to the mountains along the coast. Early in the nineteenth century other visits to the San Joaquin Valley were made both by soldiers and priests, but without increasing the knowledge of the Sierra.

It was not until the coming of the American and British trappers that a real interest in the interior became manifest. In the winter of 1826-27 Jedediah S. Smith, one of the greatest of American fur traders, entered California from Utah and crossed the Tehachapi into the San Joaquin Valley. In May, 1827, he crossed the Sierra Nevada and returned to Great Salt Lake. He was undoubtedly the first white man to cross the Sierra, but it is reasonably certain that he did not see Yosemite.

In 1833, Joseph Reddeford Walker left the Bonneville expedition in the Rocky Mountains and came West from Great Salt Lake to explore for new beaver streams. With a large party, he came down the Humboldt River (then known as Marys or Ogdens River), and crossed the Sierra by a route that brought him along the plateau between the Tuolumne and Merced Rivers. A young man named Zenas Leonard, who was clerk of the expedition, published his journal in 1839 in Clearfield, Pennsylvania; and in that publication occur the following words, which constitute unquestionably the first printed description of Yosemite Valley:

"We traveled a few miles every day, still on the top of the mountain, and our course continually obstructed with snow hills and rocks. Here we began to encounter in our path many small streams which would shoot out from under these high snow-banks, and after running a short distance in deep chasms, which they have through ages cut in the rocks, precipitate themselves from one lofty precipice to another, until they are exhausted in rain below. Some of these precipices appeared to us to be more than a mile high. Some of the men thought that if we could succeed in descending one of these precipices to the bottom, we might thus work our way into the valley below, but on making several attempts we found it utterly impossible for a man to descend, to say nothing of our horses. We were then obliged to keep along the top of the dividing ridge between two of these chasms which seemed to lead pretty near in the direction we were going—which was west—in passing over the mountain, supposing it to run north and south."

Following this expedition of Walker in 1833, no record appears of any white men visiting the upper Merced until the mining excitement, although many parties crossed the Sierra to the north and a few penetrated the range farther south. Even the Forty-niners found no attraction in the granite walls of the canyon, guessing correctly that no gold lay therein. Their activities were in the lower courses of the river and in the tributaries on either side. In this lower part of the Sierra, just above the foothills, they came in contact with the mountain Indians, and of the resultant raids and punitive expeditions you have already been told.

The story of the Mariposa Battalion and the expedition that led to the real discovery of Yosemite is best known through the book published many years later by Lafayette H. Bunnell. There are a few other sources of information, however, and these corroborate Bunnell in almost all essential particulars. Dr. Ralph S. Kuykendall has written a very interesting monograph on this subject, based on contemporary accounts supplemented by Bunnell and by other records. It has been reprinted by the National Park Service as a small pamphlet, and appears in substantially the same form in "The Handbook of Yosemite," edited by Ansel F. Hall.

To Bunnell belongs the honor of naming the Yosemite Valley. He wisely selected an Indian name and proposed it to his fellows of the battalion, who adopted it. A few years later James M. Hutchings questioned the spelling and endeavored to substitute "Yo Hamite." It is given in this form on the first pictorial representation of a Yosemite scene ever published, a lithograph of the falls in 1855. Hutchings maintained that his form was the true sound of the Indian name for grizzly bear. Bunnell's

form had the priority, however, and soon became indelibly written in the annals of the Valley. Later studies by Dr. C. Hart Merriam throw light upon the question, showing that the word for grizzly bear among the tribe that actually inhabited the Valley was more nearly as Hutchings gave it, being *Oo-hoo-ma-te* or *O-ham-i-te*, while the tribe next north of the Valley called it *Oo-soo-ma-te*.

For several years after the discovery of Yosemite Valley in 1851, only a few people visited it. In 1852, two mining prospectors were killed by Indians near the foot of Bridal Veil Falls. A punitive expedition of United States troops under Lieutenant Tredwell Moore entered the Valley, executed five of the Indians and pursued others across the mountains by Tenaya Lake and Bloody Canyon to Mono Lake. Gold was found on the eastern side of the range, and the news spread among the Fresno River camps. A party of miners, among whom was a man named Leroy Vining, visited the Mono region. Lee-vining Canyon was named at this time. James Caper Adams, the great grizzly bear hunter, camped just north of Yosemite in 1852 and visited the Valley in 1854.

The tourist history of Yosemite began in 1855 with the visit of James M. Hutchings and a small party. They were enthusiastic over the falls and cliffs and made these wonders widely known. In 1863 and 1864 the California State Geological Survey, under Josiah Dwight Whitney, explored Yosemite and the Tuolumne Meadows. Largely upon the recommendation of the Survey, the Valley was set aside by Congress "for public use, resort, and recreation," under the trusteeship of the state of California. The Valley remained under state administration until 1906, when it was consolidated with the Yosemite National Park, which had been constituted in 1890 from the surrounding territory, and has since then been under federal jurisdiction.

There is a great deal of interesting literature on the history of Yosemite which you can best learn about by inquiring at the Museum. The Park naturalist will be glad to show the books or give you references to them. The Government publications giving information about the Park can be had there or by writing to the National Park Service, Department of the Interior, at Washington.

DOCTOR RIXFORD—In dedicating this plaque to Doctor Lafayette Houghton Bunnell we must not forget the debt we owe to Doctor Howard A. Kelly of Baltimore, whose inspiration it was that gave birth to the idea of the medical profession commemorating in some fitting way the pioneering activities of Doctor Bunnell. Doctor Kelly learned that the grave of Doctor Bunnell in Winona, Minnesota, is unmarked, save for a G. A. R. emblem, and started a subscription list for a suitable monument for this "real medical pioneer." Moreover, Doctor Kelly contributed \$50 towards defraying the expense of placing this plaque in Yosemite Valley, in memory of Doctor Bunnell, who "alone of the little group that entered on a punitive expedition went eager and thrilled with the zest of discovery. He fully appreciated the opportunity, and was filled with mystery. His companions were impassive and unimpressed, while he was exulting in the glories that unfolded before them: he became its baptismal sponsor and gave the Valley its euphonious name and later wrote about it in a never failing spirit of enthusiasm. For these reasons we claim that Doctor Lafayette Houghton Bunnell was the true discoverer about March 21, 1851."

Doctor Kelly was not aware that the date of entry of the Mariposa Battalion has been accurately fixed as March 25, 1851, as Bunnell himself was uncertain of the date. We have no knowledge of the circumstances which led Doctor Bunnell to write his book, "Discovery of Yosemite Valley and the Indian War of 1851 Which Led to That Event," but much of the vagueness of his description is doubtless explained by the fact that the book was written some thirty years later and after the Valley had become famous through the published writings of J. M. Hutchings.

Doctor Kelly became interested in Doctor Bunnell in a roundabout way through a letter published in the Medical Record, November 23, 1915, from Doctor H. S. W. Barnes of Santa Ana, California, calling attention to the regrettable omission of the name of Doctor Bunnell from an article in the issue of October 26 by Doctor William Browning, entitled "Some of Our Medical Explorers and

Adventurers." By dint of much correspondence, Doctor Kelly finally secured and pieced together many items concerning the life of Doctor Bunnell, in addition to Bunnell's own published writings. His book on Yosemite, Doctor Barnes calls a "frontier classic," and his later volume, "Winona and Its Environs on the Mississippi in Ancient and Modern Days," is described as "a mine of Indian lore."

Doctor Kelly published the results of his search in *Annals of Medical History*, October, 1921, and this article is our principal source of information about Doctor Bunnell.

Bunnell was called *Doctor* because of his knowledge of medicine, but he had no diploma till long after his sojourn in California, when the La Crosse Medical College in 1864 gave him a diploma ("honorary"). The diploma issued by the college in the Republic of Wisconsin is preserved, and is in possession of the Minnesota Historical Society.

Born in Rochester, New York, November 2, 1824, his father a practicing physician, his mother a member of a distinguished family, Houghton by name, Bunnell spent most of his formative years in Detroit. Later, in La Crosse he attended clinics in the La Crosse Medical School, very much against his will. He was not interested in medicine. His was too much a roving disposition to settle down as a country doctor or even to make much of a success of business. But with scant systematic training his knowledge of medicine, derived largely by sheer observation and absorption from the medical atmosphere of his father's home, simply had to be drawn on for the benefit of his fellows who, as in the mining days of California, were often far out of reach of trained physicians. He was peculiarly and emphatically "médecin malgré lui."

In the second visit of the Mariposa Battalion to Yosemite, Bunnell had something of a medical equipment with him and received extra pay as surgeon to the expedition.

Bunnell served in the Mexican War in 1845 and in the Civil War as a hospital steward, and after he received his diploma was appointed first assistant surgeon, then surgeon, on his enlistment in the Thirty-sixth Wisconsin Infantry Volunteers.

Thus Bunnell was a veteran of three wars, in all of which his knowledge of medicine secured for him unusual opportunities and responsible positions.

He died July 21, 1903, at Homer, Minnesota, at the age of 79, and is buried at Woodlawn Cemetery, Winona.

Thus passed a strong man, whose life was an epitome of pioneering and adventure—the type of man who gave to California its peculiar character and romance—a type that did a great work and has passed on, and leaves one to wonder whether the inevitable huddling of humanity into great cities will, notwithstanding their vastly greater educational facilities, develop men of character which will ring as true.

MINUTES OF THE HOUSE OF DELEGATES, FIFTY-FOURTH ANNUAL SESSION OF THE CALIFORNIA MEDICAL ASSOCIATION.

FIRST SESSION

Held in the Tent, Yosemite Lodge, Yosemite National Park, California, Monday, May 18, 1925, at 8 p. m.

Call to Order—The meeting was called to order by the President, Granville MacGowan of Los Angeles.

Roll-Call—The secretary called the roll; forty-five (45) delegates were seated, and the president declared a quorum present.

Report of the President—The president, Granville MacGowan, stated that, as his report had been read in full to the association at the First General Session, he would therefore rule that no further report was necessary.

Report of the Council—James H. Parkinson of Sacramento, chairman of the Council, submitted the following report:

Doctor B. F. Keene—At the meeting of 1924, the report of the special committee on restoration of the grave of Doctor B. F. Keene, the first president of the society,

giving details as to specifications and costs of this work was received. The report was adopted and the committee continued with instructions to carry the work to completion. This has now been done and a brief sketch with an illustration appeared in the May number of CALIFORNIA AND WESTERN MEDICINE. It is impossible to read the minutes of the second annual meeting of the Medical Society of the State of California, February 11, 1857, or the obituary and resolutions appearing in the California State Medical Journal, October, 1856, and fail to realize that this, our first president, was of the highest type as man, physician and citizen. "A short biographical sketch," by Doctor Obed Harvey, then of Placerville, but later of Sacramento, whom several members of this society now living will recall, states that: "Four years he represented the County of El Dorado in the Senate of the State * * * * *, and had his life been spared one day longer he would again have been chosen." Of all that has been written, perhaps nothing better expresses the man as the true physician than this, probably from the pen of Doctor John F. Morse: "Although of a serious and grave cast of character, yet his heart seemed warmed towards his fellow-beings with a benevolence and confidence unmarred by suspicion and unaffected by the admonitions of experience." It is better that we depart hence while yet useful so that we be missed as well as regretted.

Bunnell Memorial

The special Committee on the Bunnell Memorial has, with the permission of Mr. Stephen T. Mather, placed a bronze plaque on a large boulder at the site of the first camp in the Valley of the Mariposa Battalion with the following inscription: "Commemorating Doctor Lafayette Houghton Bunnell, one of the first party of white men to enter the Yosemite Valley in March, 1851—he proposed the name Yosemite and was the first to proclaim its beauty and wonders to the world."

The plaque was designed by Mr. Paul Fair of Berkeley and fittingly depicts the grizzly (Yosemite), surprised at the entrance of the Caduceus, symbolizing the physician, into his native haunts. Doctor Bunnell, who had served in the Mexican War, was a member of the Mariposa Battalion organized January 18, 1851, as mounted infantry. This troop entered the valley by the "old Mariposa trail," and encamped near the meadow, now known as "Bridal Veil," on the south side of the Merced River and below the Bridal Veil falls. The plaque will be dedicated by the Society on Tuesday, May 19, at 10 a. m.

Meetings

The Council has held three regular meetings during the year; the daily sessions during the annual meeting not included. Two open meetings were held in connection with Industrial Medicine: one in Long Beach and one in San Francisco.

The Executive Committee has held nine meetings with an average attendance of six members out of eight.

Office of the Association

The office continues to function in a most satisfactory manner. The business of the association is conducted, apparently, with satisfaction to all who have come in contact with the staff.

It seems best to include in this report and to present each year certain tabulations which more graphically indicate conditions than is possible by any description. The following table shows the growth of the society for the ten-year period—1915 to 1924, inclusive, as of December 31.

Year.....	1915	1916	1917	1918	1919	1920	1921	1922	1923	1924
Membership.....	2557	2602	2699	2534	2496	3136	3484	3666	3809	3945

The Journal

California and Western Medicine continues to improve by the addition of special features and by a higher literary standard, which has been made possible by rigid selection from the abundance of material offered. To publish even the good papers that come to the office would make each issue an unwieldy volume. The request of the editor for an editorial reference committee was approved by the Executive Committee, and it is hoped by careful consideration to present, monthly, the

best in medicine from the Pacific States. Doctor Musgrave, who has made these improvements possible, continues to serve without remuneration.

The following is a recapitulation of Journal conditions from 1918 to 1924, inclusive:

Year.....	Yearly Pages Reading.....	Yearly Pages Advertising.....	% C. M. A. Dues.....	Miscellaneous Receipts.....	Disbursements.....	Yearly Profit.....	Yearly Loss.....
1918	540	552		\$ 9,468.76	\$10,908.57		\$1,439.81
1919	446	576		11,011.99	11,472.89		460.90
1920	430	624		14,015.41	13,561.96	453.45	
1921	492	720		15,917.82	19,614.10		3,696.28
1922	468	768		20,933.40	22,791.29		1,857.89
1923	542	816	\$7,812	23,200.37	28,997.49	2,014.88	
1924	720	816					

Medical Defense

Medical Defense by the society ceased as of June 30, 1924. In order to keep before the society the imminent peril of damage suits, a condensed recapitulation of the medical defense feature for the years 1917 to 1924, inclusive, is here given:

Year	1917	1918	1919	1920	1921	1922	1923	1924	Totals for 8 Yrs.
Claims (threatened suits disposed of out of court)	44	28	22	17	23	28	24	19	205
Cases (disposed of by court proceedings)	22	17	12	17	17	7	13	22	127

The following is a statement for the year 1925 as of May 1.

	Defense Only	I. D. Fund
Claims (threatened suits) pending and undisposed of.....	6	8
Cases pending and undisposed of.....	23	35
Claims (threatened suits) disposed of out of court, 1925.....	0	0
Cases disposed of in 1925.....	11	4

Financial Condition of the Association

The financial condition of the society is sound. Even with the substantial sum of \$7,812 credited to the Journal in accordance with the postal laws, the treasury shows a cash balance of \$19,040.11 as of December 31, 1924. The books and accounts of the society were audited by Lester Herrick & Herrick, and according to their report on file were found correct. All claims are audited by the auditing committee, the bills being approved by that member of the staff responsible for them. The voucher is then approved by the secretary, signed by the auditing committee and countersigned by the chairman of the council and the secretary.

Annual Assessment

In view of our continued responsibility in connection with medical defense as well as other contingencies, it is recommended that the annual assessment be fixed at \$10.

The following is a recapitulation in condensed form of the finances of the society from 1918 to 1924, inclusive, as of December 31 of each year.

RECEIPTS OF ASSOCIATION						
Year	Amt. Dues	No. of Members	Society Dues	Journal Earnings	Misc. C. M. A.	Total Receipts
1918	\$ 7	2534	\$18,157.00	\$ 9,468.76	\$3,019.08	\$30,644.84
1919	7	2496	17,262.00	11,011.99	681.36	28,955.35
1920	7	3136	21,782.25	14,015.41	909.29	36,706.95
1921	8	3484	24,104.50	15,917.82	1,006.57	41,028.89
1922	8	3666	29,000.50	18,202.91	795.26	47,998.67
1923	10	3809	37,594.00	20,933.40	1,421.69	59,949.09
Net 31,346.00						
Credit Journal 7,812.00						
1924	10	3945		23,200.37	875.86	63,234.73
DISBURSEMENTS						
Year	C. M. A. General Expense	Journal	Legal	Total	Cash On Hand Dec. 31	
1918	\$6,820.85	\$10,908.57	\$ 9,372.73	\$27,102.15	\$ 5,095.95	
1919	6,543.22	11,472.89	9,294.36	27,310.47	6,740.83	
1920	8,531.68	13,561.96	9,784.23	31,877.87	11,469.91	
1921	9,018.28	19,614.10	17,839.82	46,472.20	6,126.60	
1922	6,808.86	21,877.21	21,425.19	50,111.26	4,219.01	
1923	4,543.57	22,791.29	22,243.42	49,578.28	14,589.82	
1924	7,390.64	28,997.49	22,396.31	58,784.44	19,040.11	

Optional Medical Defense

Optional Medical Defense inaugurated by the Council under instructions from the House of Delegates, went into effect July 1, 1924, for 168 members; on May 1, 1925, the number of subscribing members was 464. This, while most gratifying in every way, is not sufficient as a self-sustaining organization on the present financial basis. There should be at least 1000 members to afford a reasonable margin of safety. Until quite recently, no member has been sued. Three suits, however, have been filed during the present month and it is inevitable that others will follow. The former name of the society has been secured and perpetuated in the new organization.

Financial Impositions Upon the Profession

The committee appointed by the Council last year has shown commendable activity in an effort to obtain for the profession simple justice in the matter of these impositions.

Federal Income Tax—The bill amends Section 214 of Revenue Act of 1924 relating to deductions in computing net income by adding the words "or profession, or in attending professional conventions of the profession of which the taxpayer is a member." It will be recognized that this includes all professions. The Council has instructed the secretary to communicate with other professional organizations, and with all State societies and with the A. M. A. to ensure co-operation and general support.

Harrison Narcotic Tax—"Through the initiative of the American Medical Association, a bill was introduced in the 67th Congress, providing for the abolition of the war tax under the Harrison Narcotic Act, and its re-establishment on a peace basis."

Two Dollar Annual Tax—This has been under consideration by the Council and at the 144th meeting the League was authorized to introduce a bill repealing the \$2 license tax and at the 74th meeting of the Executive Committee all action to repeal was deferred. What it actually means in real money to the members of the society is fairly well shown by the following table. It is assumed that the tax went into effect as of January, 1918. The membership of the society as of January 1, 1918, has been taken for that and succeeding years. On this basis a total of \$46,140 has been paid by our members.

Year	No. of Members	Tax	Real Money
1918	2534	\$2.00	\$ 5,068.00
1919	2496	2.00	4,992.00
1920	3136	2.00	6,272.00
1921	3484	2.00	6,968.00
1922	3666	2.00	7,332.00
1923	3809	2.00	7,618.00
1924	3945	2.00	7,890.00
Total to date.....			\$46,140.00

Proposed Amendments to Constitution and By-Laws

The attention of the Council was called to various conflicts between the constitution and by-laws and between the by-laws and council rulings. To harmonize the conflicting sections the necessary amendments have been submitted for consideration at this meeting. The principal change omits the controversial words "sciences allied to medicine" and keeps the California Medical Association limited in membership to Doctors of Medicine only. Associate members will be physicians who are engaged in research work or who hold federal positions, unlicensed to practice medicine in California, and hence ineligible to active membership. The requirements necessary for eligibility to office in the society are also more clearly defined in the proposed amendments, which are published on page 896 of this issue of CALIFORNIA AND WESTERN MEDICINE.

Medical Officers' Reserve Corps

At the request of the Surgeon General, U. S. Army, the Council has appointed a statewide committee of fifteen on this subject, with Doctor John Wilson Shiels as chairman. The purpose of this committee is to aid in building up a medical officers' reserve corps under

the general scheme of defense as devised and inaugurated by the War Department. The ultimate strength of the corps has been placed at 40,000. At this date 10,000 medical officers have enrolled. The Surgeon General will advise with the various state committees in classifying members in their respective states under the particular groups in which they are best qualified to function. In this way, it is hoped to avoid the mistakes that were inevitable, though most unfortunate for all concerned, during the World War. The committee will also serve as a point of contact between the army and medical profession, and as a means of communication between the Surgeon General and the California Medical Association. The chairman of the committee will present a report to the General Session Monday, May 18, 1925.

Industrial Medical Practice

At the 53rd Annual Session held in Los Angeles, May, 1924, the Council authorized the appointment of a statewide committee of 15 to investigate and report upon all phases of Industrial Medical Practice. This committee was organized into three regional groups, with Doctor Sol Hyman of San Francisco as general chairman of the committee. The committee held a conference with the Industrial Accident Commission on December 18, 1924, to discuss the new fee schedule contemplated by the Commission, and succeeded in deferring action in this matter. Two open meetings were held with the Council by this committee to discuss the progress made and to outline contemplated activities. On May 5, 1925, a post-card questionnaire was mailed by the committee to all members of the California Medical Association to ascertain those interested in industrial medicine. A formal report will be made by the chairman of this committee to the House of Delegates Monday, May 18, 1925.

Clinical Prizes

At the 148th meeting of the Council held in November, 1924, three clinical prizes were established to be competed for at the 1925 State Meeting as follows: First prize, \$100; second prize, \$75, and third prize, \$50. The chair was authorized to appoint a committee of three to formulate the necessary regulations governing such awards. It was evident that the time was too short for competition in 1925, so no further action was taken. At a meeting of the Council held May 17, this action was rescinded and the recommendation made that two prizes only be offered of \$150 each; one for original research and one for a clinical subject. If this be approved, the committee will be appointed.

History of the California Medical Association

At the 150th meeting of the Council held in February, 1925, the question of appointing a permanent committee on "Preservation of the History of the California Medical Association" was considered, and the chair was authorized to appoint such committee of from three to five members to include himself. This committee has not yet been appointed. The Council will endeavor to find men with the necessary knowledge.

Medical Radio Broadcasting

The possibilities of abuse in Medical Radio Broadcasting are so great and the need of some general rules for the guidance of our membership seemed so imperative that the Council appointed a committee to consider the question and to report. This committee, consisting of George H. Kress, chairman; Walter B. Coffey, Edward N. Ewer, Morton R. Gibbons and Granville MacGowan, submitted in February last a general report on the subject with the following specific recommendation:

"Your State Society Committee, therefore, recommends that each county unit be requested to provide for the appointment of a sub-committee on Medical Radio Broadcasting, this committee to consist of three to five members, according to the wishes of the county members; and the principles laid down in this report be carried out as fully as can be done according to the local environment."

The report was approved by the Council at its 150th

meeting, and has been transmitted to the component societies.

Prenatal Care

At the 53rd Annual Session held in May, 1924, the Council considered a series of letters then being sent out by the State Board of Health under the Shepard-Towner Act. After a conference with Doctor George E. Ebricht, president, and Doctor Ellen S. Stadtmuller, director of Child Hygiene of the State Board of Health, a committee was appointed with Doctor Reginald Knight Smith of San Francisco as chairman, to formulate a pamphlet comprising the changes desired by the Council and the membership. The personnel of Doctor Smith's committee was selected from among the obstetricians and pediatricians of the State. The first draft of the proposed pamphlet was submitted to the Council at its February, 1925, meeting, and was deemed of such importance that it was mimeographed and mailed to each member of the Council for more careful consideration and recommendations. Copies were also mailed to obstetricians and pediatricians throughout the State for comment. The returned comments have been forwarded to the committee and a final report will be made at the General Session, Monday, May 18, 1925.

National Board of Medical Examiners

The recognition of the National Board of Medical Examiners by the California State Board of Medical Examiners is under consideration and is favored by the State Board. The matter is being taken up with the Attorney General.

Income Tax Deductions

Having heard the report of the President and of the General Counsel as to action taken with regard to the proposed amendment to the present Income Tax Act, the Council commends the action of the committee in the course adopted.

Permanent Convention Headquarters

The Council having heard the report of Doctor Harlan Shoemaker, chairman of the committee on Permanent Convention Headquarters, recommends that the thanks of the society be extended to the committee for the very large amount of work it has done, and that the committee be continued.

Appointment of Reference Committee—The president appointed as members of the Reference Committee Harlan Shoemaker of Los Angeles, chairman; O. D. Hamlin of Oakland and Fred R. Fairchild of Woodland.

Report of Auditing Committee—Morton R. Gibbons of San Francisco, acting chairman of the Auditing Committee, stated that the books of the association had been audited by Lester Herrick & Herrick of San Francisco, certified public accountants, who certified that all accounts for the year 1924 were correct. He then read the items of total receipts and disbursements for the year, and stated that the reports of the auditors were on hand and could be examined by anyone who desired to do so.

Report of Committee on Scientific Program—Emma W. Pope of San Francisco, as chairman, submitted the following report of the Committee on Scientific Program:

The program of the 1925 meeting reflects the careful work of section officers in the selection of diversified topics and of able speakers. It is a pleasure to acknowledge the exceptional co-operation of section officers for 1925.

There are certain facts that should be regularly emphasized in the report of the chairman of the committee on Scientific Program; the most important being that each annual program closes on February 15, goes to press March 20, and is printed annually in the April copy of California and Western Medicine. Long after the April journal, with its completed program has been published, applications for space come straggling into the office.

Every member who desires to speak at an annual session should apply to his proper section secretary before the first of any given year. The section chairman and secretary, acting in conjunction with the Program Committee, control the program of their section. In every issue of California and Western Medicine,

the names of the section officers are listed, under the Directory of Medical Organizations.

All general meetings and many section meetings have as speakers invited guests. The names of Mr. W. B. Lewis, superintendent of the Yosemite National Park, and of Mr. Francis P. Farquhar of the Sierra Club on the Bunnell Memorial Program; of Doctor David Starr Jordan, president emeritus of Stanford University, on the League Program; of Doctor John Phillips from the Western Reserve University and Cleveland Clinic, on the program of the Fourth General Session; of the Honorable George F. McNoble, president of the California Bar Association, on the Optional Medical Defense Program; of Doctor Verne C. Hunt of the Mayo Clinic, on the General Surgery, Urology and Western Branch of the American Urological Association Sections; of Doctor Karl Meyer from the Hooper Foundation, on the General Surgery Program, are all names of men eminent in their various specialties. It is fitting that we make special acknowledgment to them for their interest and their part in making this the 54th Annual Session a success.

Report of Secretary—The secretary, Emma W. Pope of San Francisco, presented the following report:

The history of every individual, organization or nation is always a history of high-lights—of the times of great change, or stress, or conflict, or happiness. The quiet periods of even development go unnoted. In the history of the California Medical Association, 1924, is such an unemphasized period—a year of steady growth in membership, in accumulated working possessions, in society activities and in reserve funds.

The total increase in membership during 1924 was 173, which, depleted by 37 transferred and 35 deceased members, left a net total of 101. An increase of 361 members since the last apportionment of the A. M. A. made in 1922, entitled the California Medical Association to one extra representative in the body of 175 State delegates to our national organization.

During the year five 600-watt Bausch & Lomb lanterns and silesia screens were purchased for society use. These lanterns will eliminate much confusion at our annual meetings and will meet an urgent county society need in the extension service work. At this time, it is not inappropriate to state that no invitation is extended individually to members to join the Extension Service—all members are eligible. Notices have at times appeared in California and Western Medicine asking that those who desire to talk before county societies furnish this office the titles of those papers they are prepared to present, and whenever it seems warranted, new extension lists, including these names, will be printed and furnished to county secretaries.

The publication of a directory of the California Medical Association has met with hearty approval. The next issue, to be published in January of 1926, will list the home address and office and home telephone numbers. Needless to say, this will involve much additional labor, and complete and accurate information will be possible only through the individual co-operation of our members.

The restoration of the neglected grave of our first president, Doctor B. F. Keene, at the pretty little hillside cemetery of historical Placerville, and the placing in Yosemite Valley of a memorial plaque in honor of Doctor Lafayette Houghton Bunnell, were worthy society activities.

The report of the work of the Placement Bureau is never quite accurate, due to the fact that very often physicians whom we have placed, or doctors for whom we have secured assistants, fail to report to this office the final outcome of the Placement Bureau work. By accident only, do we at times learn that the physician has secured the position to which the Placement Bureau has sent him. We have, however, an accurate record from thirty-five physicians, ten nurses and two technicians. The value of this service to young graduates cannot be over-estimated. It is often the connecting link to the worthwhile licentiate between his college work and his established office. The attention of the membership is called to the large number of office assistants and laboratory technicians on file with the hope

that more members in need of nurses and technicians will avail themselves of the Society's Placement Bureau.

Optional Medical Defense has now at the close of its first year, one-third the membership that the Indemnity Defense Fund had at the termination of its seven years of existence. It is an interesting commentary that those members who are most keenly alive to the need for this service, as is evidenced by their membership in it, are also most keenly alive to the necessity of lessening the number of alleged malpractice suits, and plan an educational campaign among the members for the avoidance, whenever humanly possible, of the causes that lead to these alleged malpractice suits.

There has been added \$4500 to the \$14,500 on hand January 1, 1924, making a total reserve of approximately \$19,000. The general society expense was increased by \$2800, of which about \$2000 was expended in the purchase of lanterns and in the publication of our directory—the remaining \$800 being due to an increase in salaries and office supplies. Legal expense did not decrease as was hoped, but remained almost the same as that of 1923, though, through the expenditure of this amount, twenty-two court cases were disposed of in 1924 as against thirteen in 1923. Journal expenses were greatly increased due to the expansion of the Journal before the present raise in advertising rates had become effective. Because of the present postal ruling that one-half of the subscription price of a fraternal journal must be credited that journal, \$2 per member, or \$7800, was so credited and thereby shows a \$2000 Journal gain for 1924. The new Journal advertising rates became effective January 1, 1925, and to May 1 had absorbed all Journal expenses but \$261. It is, therefore, highly probable that the Journal, if not further enlarged, will report for the coming year a much greater Journal gain.

Of the 3945 members at the end of 1924, 3566 are reported in good standing as of May 1. These statistics are rather indicative of the fact that those opposed to the amount of dues must come from a very small minority of the California Medical Association. It is interesting to learn authoritatively of what other states are doing. The annual dues of Washington, D. C., and of Oregon lead at \$20, Texas comes next with \$15, Michigan, Kentucky, New York, Wyoming and California \$10, Wisconsin \$9. Dues in other states range from \$3 to \$10. "Ohio," and this I quote from Doctor Olin West, "with a very splendid organization and a good journal, maintains its annual dues at \$5. It is to be remembered, however, that Ohio has a membership of more than 5000. The state associations that maintain their dues at the lowest figures—\$3 or \$4—are, as a general thing, not nearly so active as those with higher dues."

When a man erects a building he guards by insurance against the loss of his invested capital. Medical dues are just such insurance and protect the capital of the years and the money invested in your profession. Were there no medical associations to uphold the ethics and educational standards of the medical profession and to educate the public in scientific medical truth, the dark ages of medical empiricism and quackery would be upon us.

The officers of your association, at their own expense, attend all Executive Committee meetings and all Council meetings held throughout the year. They, who thus incur many times the financial indebtedness of the regular membership, patiently debate the question of the reduction of dues. Does it not seem fitting that the membership, who seldom question the cost of a good dinner, or the loss of a misshot golf ball, or the price of an adventurous jaunt into the wilderness, by approving once for all the policy of levying a yearly assessment a little in excess of actual needs sanction through this regular yearly reserve, the undertaking of such society activities as seem desirable and worthy in the eyes of your appointed representatives.

In conclusion, let me again emphasize that the State office is information desk, complaint department, placement bureau, membership, bookkeeping and advertising department and general utility office. In doubt or debate on any subject, write or visit your office. Explanation clarifies hazy understanding; sane discussion modifies antagonistic beliefs; and whether the belief of the member or of the office be changed, the resultant effect is

beneficial and advantageous to the harmonious unity of the association.

Report of Editor—The president announced that, as the following report of the editor had been presented before the First General Session, it would not be read at this session.

The financial condition of CALIFORNIA AND WESTERN MEDICINE is shown in the annual statement of the California Medical Association. It is an encouraging one, and it ought to be still better from year to year in spite of the increasing cost of paper and printing and the very sharp increase in postal rates that recently became effective.

Growth of the magazine has been equally satisfactory in all other respects, as is indicated by the following figures:

Number of pages published in 1924 (Vol. XXII, 12 issues), 1536, 654 pages solid reading matter, sixty-six pages reading matter in advertising pages, 816 pages advertising, including directories of medical organizations, front cover, index pages, etc.

Average number of words to page, 1200, making a total of 864,000 words of reading matter, exclusive of advertising.

Circulation over 5000, and more widely distributed than ever before.

Number of contributors' articles published in 1924, 117.

Number of manuscripts on hand, accepted but unpublished, 105.

Number of manuscripts declined in 1924, nineteen. Many others have been returned to the authors with suggestions for more or less extensive revision and not all of these will come back to us.

In a word, CALIFORNIA AND WESTERN MEDICINE is now a metropolitan medical magazine widely read and widely quoted in other medical and even non-medical literature. This desirable situation has been brought about by the wise and liberal policy of the Council, Executive Committee, officers and employees of the California Medical Association, representing you, the owners of the magazine. *Your policies are fruitful chiefly because of a successful co-ordination of editorial, advertising and publishing forces.*

I want to invite your attention to these three fundamentals of successful publication because you as the owners of the magazine need to consider the problem with particular reference to its future.

My own work, although delightfully interesting and even entertaining, must eventually be passed on to someone else. It will require all of the time of an editor to do as they should be done the things that only the editor, who is unavoidably responsible for his publication, can do. I ask you to consider this matter carefully and make preparations to meet eventualities.

More than to any other factor the quality and continued growth of CALIFORNIA AND WESTERN MEDICINE is due to the unusual ability, hard work and loyalty of my assistant, Miss Sue Van Wagenen. Miss Van Wagenen handles entirely upon her responsibility all the routine pertaining to advertising; collecting; securing discussion, assembling and arranging for the publishers all contributors' essays; in co-operation with the publishers she solves that most difficult of problems, the *mechanics* of the Journal, and she discharges many, many other important functions which usually have the personal attention of an editor. She is overworked and inadequately remunerated. Both of these situations should be corrected, even when considered solely in the interest of CALIFORNIA AND WESTERN MEDICINE.

From a financial standpoint, advertising and service to advertisers is the most important function of any publication. Ours is most ably handled by Mr. L. J. Flynn in the western field and by the Co-operative Medical Advertising Bureau in the national field. Mr. Flynn devotes practically his entire time to CALIFORNIA AND WESTERN MEDICINE and Better Health Magazine. He has developed and is still developing profitable and highly desirable lines of advertising among western clients. Flynn not only sells advertising but service to

advertisers as well. In this he has the support of the editor and your executive committee. It is the eternal attention to advertising *service* by a competent representative that enables California and Western Medicine to carry the largest amount of ethical, carefully edited and censored advertising of any medical magazine published.

From an esthetic and general appeal standpoint, the most important problem of any magazine is one for the publishers. This problem is being, and has been, handled for over twenty years in a highly commendable manner by the James H. Barry Company, under the immediate supervision of Mr. William H. Barry, who serves us wisely and well without additional compensation as Superintendent of Publications.

However, beautiful settings, silver and service do not make a meal. Nor do comparable qualities make a magazine. The meal depends for satisfaction upon the food, and the magazine is dependent upon the quality and method of presentation of the matter supplied by its contributors. Thus the development of California and Western Medicine—or any other magazine—is primarily dependent upon the contributors. In this instance, upon you. The measure of the scientific value of the magazine and of success in general in the end, also must be measured by you, our readers, and I leave the matter there.

Problems—I could interest you and probably entertain you with some of the manifold problems of the editor, but this would be at the expense of brevity and therefore of the value of this report.

There is one problem of major importance—and it is your problem—about which I need your instructions. It is, what shall we do about the large number of contributions now on hand and the others that are arriving almost daily? As shown above we now have on hand accepted material enough—much of it already in type—to supply our publication in its present size for a year. In addition to this and aside from the scores of essays accumulated at medical meetings, the routine mail brings us ten or more papers a month, or about enough to keep us supplied. How shall we solve this problem? Shall we still further increase the size and consequently the cost of the magazine; shall we issue it more frequently, or shall we become much more discriminating in the material accepted for publication? This is your problem and your instructions as to policy are invited.

In my opinion—and it is only an opinion—the time is not ripe for a weekly or semi-monthly magazine; the size of each issue should be left entirely to the judgment of the editor and the executive committee; and the editor, with the advice of his Editorial Councilors, should be formally instructed to select and accept for publication only what can be used of the best and most appropriate from what is offered. This under such policies as the Council and Executive Committee may from time to time prescribe.

Assuming intelligent judgment and not over a reasonable amount of fallibility on the part of the editor and his advisors, this policy should lead to the production of a medical magazine of increasing usefulness and attractiveness. It does manifestly increase the problems and responsibilities of the editor. But that is what editors are for. The wise action of the Council in providing the editor with a confidential council of such fellows as he may elect helps, but does not eliminate, the grief inherent in accepting one author's work and declining that of another. The names of the editor's some fifty councilors are kept confidential between him and each advisor, for obvious reasons.

Report of Committee on Industrial Medical Practice—Sol Hyman of San Francisco, as chairman of the Committee on Industrial Medical Practice, presented the following report:

In speaking to you upon the work of the committee on Industrial Medical Practice, we shall at first endeavor to give you a brief review of the situation in this field as it exists in California at the present time.

Review of the Situation

From many interviews with men in and out of the

industrial field your committee has found that the evils connected with this work, so far as the medical profession is concerned, fall into two main groups:

1. So-called unethical practices such as advertising, soliciting, establishment of dressing stations, use of unapproved cards, etc.

2. Fee cutting both by physicians and insurance carriers. In this group might also be placed overcharging.

The committee on Industrial Medical Practice, feeling that group two, fee cutting in all of its phases, is by far the more important issue, has directed its work along these lines.

The fee cutting evil presents itself in a variety of forms, the principal of which are:

1. Apparently charging according to the fee-schedule, but not entering all of the items, such as omitting a certain percentage of the visits made.

2. Taking cases upon a flat rate basis for certain groups of cases, the flat rate being based upon what the claims adjustors deem to be the average rates the carriers can pay.

3. An agreement to work for a given percentage rate of the fee-schedule.

4. Contracting to work for a certain percentage of the premiums.

5. Not charging in full for what is done, i. e., charging office rates for hospital visits, giving hospital attention at cost, omitting charges for repeated radiograms, dressings, etc.

6. Taking of employment by lay organizations.

7. Accepting salaries for responsible positions.

It is clear that all of these practices have but one end in view: To make such a showing with the insurance carrier so that, in so far as can be gotten by with it, the work will go to the physician or organization which is able to save the most money for the carrier.

It is also clear that the progressive application of the above lack of co-operation on the part of the members of the profession must inevitably, and has already done so, lead to the concentration of this work in the hands of a few organizations which, because of large volume and reduced overhead, can and do serve the insurance carriers in a manner to their financial liking. Let it not be understood that your committee is criticizing adversely the existence of either small or large organizations devoting themselves to industrial medicine. It is discussing such organizations which underbid the fee-schedule in order to obtain the work.

As a corollary of the practice on the part of members in our association of underbidding and competition there has naturally developed the employment of solicitors, the attempt by correspondence and otherwise to take the work away from those who have it and the numerous other practices which can be classified under the general group, unethical.

The state of affairs has been well expressed by one industrial surgeon, who said that the whole practice of industrial medicine is degrading, and that all that he can hope to do is to keep himself at the upper limits of degradation.

Insurance Carriers—The insurance carriers are now in an apparently controlling position strategically and come fairly close to being able to dictate the rates at which industrial medical practice shall be compensated. Where necessary or expedient full schedule rates are paid, and where not necessary or expedient they demand and receive medical attention to the injured workman upon a basis of flat rates, premium percentages, fee-schedule reduction and salaries. They are able to, and do, transfer the work from one man to another over night if the desired reductions are not made. They are unwilling to acknowledge the rising cost of the medical services in line with the rising cost of all other commodities. They are unwilling to recognize that they have become educated to the value of better and more extended medical services in order to lower their compensation payments, and that consequently more must be paid for such services. They are unable to reduce their overhead in the matter of rents, advertising, brokerage, office supplies and clerical help, but see a fertile field for reduction in medical fees and

cultivate it. Some of the companies recognize the value of high grade service, adequately compensated, and maintain medical organizations of the highest rank, while others are unable to see further than the ledger.

The State Compensation Insurance Fund, the company doing the largest business in the State, about 40 per cent of the whole, and which returns dividends to its policy holders, is making a definite campaign for more business based upon the premise that it furnishes medical services at a low cost and thus is able to return larger dividends to the advantage of the policy holders. The fund has in process of development a central hospital in Redding to serve nine northern counties, to which are to be sent all of the hospital cases in these counties—a not inconsiderable industrial area. This will not alone cause a great disturbance and loss to the medical community, in that many of the practitioners in this district have made large investments in hospitals and apparatus for the care of these cases, but there will result a definite dislocation in the social aspect of these communities. Well equipped young men cannot be expected to look to these fields in which to settle and become factors. Doubtless should this scheme eventuate successfully it will be inaugurated more or less throughout the State. It will probably reduce, in a measure, the cost of compensation insurance; but is it, after all, the most economical procedure all round for the people of these communities? Will those away from the location of the central hospital be as well cared for as heretofore? Is this difference in care worth the few dollars saved in compensation insurance?

From our numerous interviews we gather the impression that the State Compensation Insurance Fund arbitrarily cuts the fees more than does any other company. We cannot state this positively to be the fact, but we can state that the committee has received many, many more complaints concerning this company than that of any other. Much of the work previously in the hands of the Medical Director is now in the hands of a layman. We note particularly that attitude of this carrier because it is a public organization, whose existence is the result of a popular vote, and whose purpose in being brought into being was that of an upholder of standards.

The Industrial Accident Commission—The Commission was written into the Workmen's Compensation Act as an impartial body to represent the State, that is all of the interests involved in the application of the Act, and as the trustees of the State Compensation Insurance Fund. In the ordinary routine work, that of adjudication of claims, etc., the committee has not come in contact with the Commission.

Last December the Commission proposed a new and comprehensive fee-schedule based upon flat rates and weekly rates of compensation for medical and surgical services. At the request of this committee the point of view of the profession in opposition to this type of schedule was presented to the Commission. The hearing was attended by the representatives of organized labor who also voiced their opposition to flat fees and weekly compensation. The chairman of the Commission then assured us that no fee-schedule would be adopted without notification of and consultation with this committee, which in turn assured the chairman of its readiness to co-operate with the Commission at all times. To date there have been no further meetings on this subject.

The campaign of the State Compensation Insurance Fund to acquire business on a basis of a more economical administration and the establishment of central hospitals to the general dislocation of social and medical order in the communities affected, we must assume have the sanction of the Commission as the trustees of this fund.

Labor—The man most vitally affected and in whose interest the Act was designed is the working man. The officers of the State Building Trades Council and Affiliated Unions and of the other State labor organizations assure us of their definite interest and willingness to co-operate with us in any effort to improve the medical services received by injured working men under the Act. They realize, however, that many of the problems are purely or mainly professional, and express themselves very certainly that any plan must come from within the

profession and have its whole-hearted support. If the medical profession can present an undivided front then they are willing and ready, in the interest of the injured working man, to do their full share. They regard the problem as one affecting the whole State, but specifically the doctor and the injured working man.

The Plan—In attempting to pave the way for the plan submitted by your committee at previous meetings of the Council whereby it was hoped that industrial medical practice might be put on a proper ethical basis by means of co-operation among the insurance carriers, the public as represented by the Industrial Accident Commission and the medical profession as represented by this association, the committee has encountered an obstacle which it has been able but partially to surmount only in the last month. As previously reported the claims attorneys in the San Francisco (Northern California) jurisdiction have expressed themselves as in favor of the idea proposed and are ready to discuss with us the details for carrying the proposed scheme into effect; but we have up to very recently been unable to interest the claims attorneys of the Los Angeles (Southern California) jurisdiction sufficiently even to allow a representative of the association to come before them. Finally, by dint of repeated arguments, a meeting was arranged and several representatives of this committee appeared before their organization in Los Angeles and discussed with them our plans. Although the organization in San Francisco voiced its approval of the principles and objects of our scheme, the Los Angeles group expressed no opinion, but appointed a committee to deal with the matter. Here the matter stands at the present time. It is clear to the committee that whatever plan be adopted can only be effective and made to go if that portion of the medical profession interested in this type of work wants it, and wants it badly enough to sacrifice something for it. It is also clear to the committee that if the profession is able to present an undivided front, each man having the sincere and real backing of his entire group, that all rebating, fee cutting and dictation by the insurance carriers can be stamped out overnight. If the interested membership of this organization wants this, its committees can accomplish something. If it does not want it, its committees are useless and helpless.

The Ballot—In order to form some sort of an estimate of the tenor of feeling within the association a ballot was taken. Sixteen hundred and thirty-four ballots were returned, representing about 40 per cent of the membership of the association. Three hundred and ninety-eight declared themselves as not interested in industrial medicine; 1135, or about 98 per cent of those directly interested in this type of work, are willing to subject themselves to the actions and decisions of the association, while twenty-two, about 2 per cent, state that they are unwilling to have their freedom of action restricted. While this ballot is perhaps indicative, the committee is somewhat in doubt as to its true meaning because, while the vote was large, there remains always the question as to the feelings of the 60 per cent who did not return an opinion.

Possibly the percentage of those who state that they will not abide by the decisions of their group can be somewhat reduced after a better understanding of the problem, but we must be alive to the fact that very few non-conformists can wreck any plan that is based upon confidence and co-operation.

The general membership of the association had but little notion that this committee has been at work upon this problem until the ballot-cards were circulated.

Summary—The industrial medical situation is not alone critical; it is disagreeable and dirty. Within the ranks of our own profession are intrigue and connivance. There is no loyalty to group and no adherence to standards. Every man is for himself and the devil take the hindmost. The ethical standards, if such they can be called, of commerce are dominant. The end justifies the means.

The individual industrial physician says that he is driven to these extremes because the association gives him no support and does not discipline the malefactors. He cannot resist the tide single-handed. Driven by economic necessity he must fall into line. Competition

necessitates his lowering of standards, much as he deprecates it. He is of the opinion that a group of men meeting in this room have it in their power to pass some resolutions and create a millennium. He fails utterly to realize that any policy of this association can be instituted only when it is the policy of the membership.

This brings us to the crux of the situation. Can the Council or the House of Delegates, now and here, put into operation *any* formulated plan to which the members of this association will adhere? Is each and every individual member ready and willing and desirous to make the fight, for a fight it will be, for several years in order that the position of medicine in the industrial field be placed on a professional rather than a commercial basis, where it now is? The present situation is the creation, not of any California Medical Association, but of the members of that association. Its correction lies solely in the hands of these same members. Is our moral fibre such that a disagreeing minority will resign itself to the will of the majority? Are we sure enough of ourselves to know what we want and to go after it?

It would seem, from the ballot, that a large interested majority can answer these questions affirmatively. Can we be satisfied that this ballot is a true reflection of the attitude of the society? What is the attitude of the 60 per cent who did not answer?

So the situation as it stands today is thus: The principal evil in the industrial medical field is fee-cutting in one form or another. The blame lies within our own ranks. The result has been a tearing down not alone of medical, but of all standards, placing the insurance carriers in the control of the situation. The indications for the future are along the lines of intense concentration with still further reduced compensation, viz: Salaries. The remedy lies in our hands; application depends upon just one factor, the moral fibre of the membership of this association.

With all of the foregoing in mind, does the membership of this association really want the situation remedied? Can it present not alone in its statements but in its actions, an undivided front, an unbreakable phalanx? The answer to these questions your committee must have. It is time for the association to speak.

In order that those county units and sections who may wish to actively engage in attempting to remedy some of the abuses that now exist in Industrial Medical Practice, may have a general foundation of principles upon which to base their actions, the Committee of Fifteen on Industrial Medical Practice of the California State Medical Association recommend that the association take definite action, declaring the following practices as related to Industrial Medicine unethical:

1. Price cutting below the regular accepted fee-schedule either directly or indirectly.
2. Fee splitting of any kind, either directly or indirectly.
3. Rebating fees or any portion of a fee, either directly or indirectly.
4. The solicitation of business by lay or other employees.
5. The advertising by individuals or by hospitals other than that allowed by the code of ethics of the American Medical Association.
6. To be employed in any capacity either on salary, fee or retainer, or as consultant by any institution or corporation or group doing industrial medicine that is owned or controlled by laymen and operated for profit.

Should further questions arise, the committee stands ready to consider them and to present recommendations at subsequent Council meetings.

Report of Committee on Medical Officers' Reserve Corps—In the absence of the chairman, John Wilson Shiels of San Francisco, John Homer Woolsey of San Francisco, as a member of the Committee on Medical Officers' Reserve Corps, presented the following report:

San Francisco, California, May 15, 1925.

Meeting of the General Committee of the Medical

Officers' Reserve Corps, present San Francisco Surgical Section as follows:

J. Wilson Shiels, M. D., Chairman, Colonel, 291 Geary street, San Francisco; Harry G. Ford, M. D., Colonel, University Hospital, San Francisco; Clarence Quinan, M. D., Lt. Colonel, 2512 Washington street, San Francisco; Walter H. Winterburg, M. D., Lt. Colonel, 516 Sutter street, San Francisco, and John Homer Woolsey, M. D., Major, 135 Stockton street, San Francisco.

Object—The education and information of the Medical Profession of the State of California relative to the National Medical Military affairs.

Program

(1) Inclination and better acquaintance between members of the committee.

(2) That the committee shall work at all times in close co-operation with the chief medical officer of the Ninth Corps area and request that he be a member ex-officio of this committee.

(3) It is the sense of the committee that there shall be a Medico-Military meeting at least once per year in each County Medical Society of the State. This meeting to be arranged for by the local representatives and aided by the State Committee.

(4) Request for a regular definite space in the Journal—"California and Western Medicine." This space will be filled subject to the approval of the editor of the Journal by the member of the State Committee appointed as a special editor.

(5) That one person be appointed within each County Medical Society by the General Committee subject to the approval of the respective County Medical Society president.

Unfinished Business—There was no unfinished business to come before the House of Delegates.

New Business—In accordance with the rules of the association, the following resolutions were presented and referred to the Reference Committee. For text of these resolutions and final action by the House of Delegates, see minutes of the second session.

Resolution No. 1. Amendments to Principles of Medical Ethics of A. M. A.—Presented by Harlan Shoemaker of Los Angeles.

Resolution No. 2. Research in Intestinal Parasitism—Presented by Lyell C. Kinney of San Diego for the San Diego County Medical Society.

Reading and Adoption of Minutes—The minutes of this session were read and, on motion of James H. Parkinson of Sacramento seconded by Joseph Catton of San Francisco, were approved.

Adjournment—There being no further business, the House adjourned to meet at 8 p. m. on Wednesday, May 20, 1925, in the same place.

MINUTES OF THE HOUSE OF DELEGATES SECOND SESSION

Held in the Tent, Yosemite Lodge, Yosemite National Park, California, Wednesday, May 20, 1925, at 8 p. m.

Call to Order—The meeting was called to order by the president, Granville MacGowan of Los Angeles.

Roll-Call—The secretary, Emma W. Pope of San Francisco, called the roll; fifty-eight delegates were seated, and the president declared a quorum present.

Place of Meeting for 1926—The chairman of the Council, James H. Parkinson of Sacramento, announced that by unanimous action of the Council, the invitation of the Alameda County Medical Society to hold the 1926 meeting in Oakland had been accepted.

Report of Committee on Arrangements—The chairman of the Committee on Arrangements, James H. Parkinson of Sacramento, announced that the number of members registered at 5 p. m. today was 387, and the number of persons in attendance at the convention 824; and that the number present at the 1922 meeting in the Valley was only 400. Doctor Parkinson read a letter from the Yosemite National Park Company expressing their appre-

WILLIAM TAYLOR MCARTHUR
President-Elect 1925-1926

ciation at having the 1925 convention of the California Medical Association in Yosemite. He then requested the privilege of the floor for Doctor George Franklin Shiels of San Francisco, who was present at the personal request of Colonel Edward L. Munson of the Ninth Corps Area.

Medical Officers' Reserve Corps—George Franklin Shiels, as the personal representative of Colonel Munson, then addressed the House of Delegates briefly on the purpose and aims of the Medical Officers' Reserve Corps.

Election of Officers

President-Elect—William T. McArthur of Los Angeles was nominated for president-elect by William Duffield, Los Angeles. The nomination was seconded by Joseph Catton, San Francisco, who then moved that the nominations be closed; such motion being seconded by James H. Parkinson, Sacramento; and the secretary instructed to cast the ballot. The secretary cast the ballot, and the president declared William T. McArthur elected president-elect for the year 1925-1926.

Vice-President—Thomas F. Madden of Fresno was nominated for vice-president by Fred R. De Lappe, Modesto, such nomination being seconded by Lyell C. Kinney, San Diego.

Joseph Catton of San Francisco was nominated by Fred Rodenbaugh, San Francisco; such nomination being seconded by C. H. Church, Yosemite.

There being no further nominations, the president announced that the House would proceed to ballot, and appointed William Bowman, Los Angeles, and Charles L. Curtiss, Redlands, as tellers. Fifty-eight ballots were cast as follows: Joseph Catton, San Francisco, 32; Thomas F. Madden, Fresno, 26. The president then declared Joseph Catton elected vice-president for the ensuing year.

Councilors

Second District—William H. Kiger of Los Angeles was nominated by Harlan Shoemaker, Los Angeles, to succeed himself as councilor for the Second District. The nomination was seconded by Dudley Smith, Oakland. On motion of William Duffield, Los Angeles, seconded by H. A. L. Ryfkogel, San Francisco, the nominations were closed, and the secretary instructed to cast the ballot. The secretary cast the ballot, and the president declared William H. Kiger elected councilor for the Second District for the ensuing three years.

Fourth District—Fred R. De Lappe of Modesto was nominated by Church, Yosemite, to succeed himself as councilor for the Fourth District. The nomination was seconded by Harry E. Alderson, San Francisco. On motion of Morton Gibbons, San Francisco, seconded by Alderson, San Francisco, the nominations were closed, and the secretary instructed to cast the ballot. The secretary cast the ballot, and the president declared Fred R. De Lappe elected councilor for the Fourth District for the ensuing three years.

Eighth District—James H. Parkinson of Sacramento was nominated by C. B. Jones, Sacramento, to succeed himself as councilor for the Eighth District. The nomination was seconded by Fred R. Fairchild, Woodland. On motion of T. C. Edwards, Salinas, seconded by R. A. Terry, Los Angeles, the nominations were closed, and the secretary instructed to cast the ballot. The secretary cast the ballot, and the president declared James H. Parkinson elected councilor for the Eighth District for the ensuing three years.

Councilor-at-Large—O. D. Hamlin of Oakland was nominated by Dudley Smith, Oakland, for councilor-at-large to succeed himself for the ensuing three years. The nomination was seconded by R. T. Legge, Berkeley.

Robert Peers of Colfax was nominated by R. R. Newell, San Francisco, such nomination being seconded by R. T. McGurk, Stockton.

There being no further nominations, the president declared the nominations closed, and instructed the tellers, William Bowman, Los Angeles, and Charles L. Curtiss, Redlands, to collect the ballot. The secretary announced that fifty-five ballots had been cast as follows: Robert Peers, Colfax, 31; O. D. Hamlin, Oakland, 24. The president then declared Robert Peers elected councilor-at-large for the ensuing three years.

Member of Committee on Scientific Program—Roland E. Skeel of Los Angeles was nominated by Harlan Shoemaker, Los Angeles, as a member of the Committee on Scientific Program for the ensuing four years. William Duffield, Los Angeles, seconded the nomination, and then moved that the nominations be closed and that the president declare Doctor Skeel elected a member of the Committee on Scientific Program by unanimous action of the House of Delegates. The secretary cast the ballot, and the president declared Roland E. Skeel unanimously

JOSEPH CATTON
Vice-President 1925-1926

elected a member of the Committee on Scientific Program for the ensuing four years.

Delegates to A. M. A.—The chairman of the Council, Parkinson of Sacramento, advised the House it was impossible for the House of Delegates of the C. M. A. to elect delegates to the A. M. A. at this session and have proper representation at the National Convention and, therefore, the Council, at its 150th meeting held in San Francisco, February 14, 1925, had elected Hans Lisser of San Francisco to fill the unexpired term of T. C. Edwards, Salinas, who had resigned, and the Council had elected as delegates to the A. M. A. for the ensuing two years the following: Albert Soiland, Los Angeles; Robert V. Day, Los Angeles; Lemuel P. Adams, Oakland; and as alternates to the A. M. A. for the ensuing two years: Charles D. Lockwood, Pasadena; Robert Pollock, San Diego; O. D. Hamlin, Oakland.

Parkinson, Sacramento, then moved that the House of Delegates ratify and confirm the election by the Council of these delegates and alternates to the A. M. A. Alderson, San Francisco, seconded the motion. The motion was adopted unanimously.

Delegates to the A. M. A., with their corresponding alternates, are as follows:

Victor G. Vecki, San Francisco, 1925; alternate, C. Van Zwalenburg, Riverside, 1925.

Hans Lisser, San Francisco, 1925; alternate, William E. Stevens, San Francisco, 1925.

Albert Soiland, Los Angeles, 1925 and 1926; alternate, Charles D. Lockwood, Pasadena, 1925 and 1926.

Robert V. Day, Los Angeles, 1925 and 1926; alternate, Robert Pollock, San Diego, 1925 and 1926.

Lemuel P. Adams, Oakland, 1925 and 1926; alternate, O. D. Hamlin, Oakland, 1925 and 1926.

Report of the Reference Committee

Harlan Shoemaker of Los Angeles, chairman of the Reference Committee, presented the following report:

1. Address of the President—The address dealt, in a very timely manner, with the existing conditions of the profession and what constitutes the practice of medicine. Doctor MacGowan reviewed, in a broad way, the problem of industrial medicine and its relation to the profession. He surveyed the relation of chemistry and bacteriology to the clinical arts and gave prophetic advice regarding the Volstead Act. He paid a fine tribute to Doctor Lafayette Houghton Bunnell and Yosemite Valley. He touched on the subject of taxation upon the profession for professional expenditures, concluding a stewardship well performed.

2. Address of the President-Elect—The address is the story of the layman, cultural education and specialism. Doctor Ewer cleverly dissected the character of one of the late popular novels as an illustration of how a layman views cultural education in medicine and specialism. Quoting John J. Abel, "There should be in research work a cultural character, an artistic quality, elements that give to painting, music, and poetry their high place in the life of man," and deploring the cultivation of ultra specialism, the lack of the distribution of young doctors in rural districts, and suggesting some causes and corrections to equalize this great economic loss.

3. Report of the Editor—The committee recommends that the report be accepted and that the felicitations of the members, the House of Delegates, and the Council be extended to Doctor Musgrave for his indefatigable efforts in behalf of the California Medical Association and CALIFORNIA AND WESTERN MEDICINE, and that the problem of the Journal as to size and the frequency of the publication be referred to the Council for its recommendation.

4. Report of the Legal Department—The committee recommends that the report be accepted and the members, the House of Delegates, and the Council extend their commendation to our Honorable Counsel, and that it be the sense of this meeting that the publicity shall be combined with the active solicitation on the part of the members present to extend and fortify the Association on Optional Defense with the points, as suggested by Mr. Peart.

5. Report of the Council—The committee commends the report of the Council and recommends a topographical redistribution of the Councilor Districts that would give better contact with the Councilor and his District. The

committee commends the compliance with the second-class postal laws for the support of the Journal. The committee notes with pleasure that the society is solvent, with a comfortable balance as of December 31, 1924. The committee commends the annual assessment of \$10. The committee recommends the adoption of the amendments to the Constitution and By-Laws as read in the report of the Council.

6. Report of Committee on Scientific Program—The committee recommends that the report of the Scientific Program Committee be accepted, and urges greater cooperation of the other members of the committee with the secretary.

7. Report of the Secretary—The committee commends the report of the secretary and voices the unanimous approbation of the society.

8. Report of Committee on Industrial Medicine—The committee recommends, having in mind the factors of the foregoing report, that the acts of the committee be approved, and that the committee continue the preparation of a plan to correct the evils of industrial medicine and in addition that the rules appended to the aforesaid report be referred to the Council and the attorney for the association for codification and enforcement.

9. Medical Officers' Reserve Corps—The committee recommends that the report of Doctor John Wilson Shiels be adopted.

10. Resolutions—Resolution No. 1. **Amendments to Principles of Medical Ethics of the A. M. A.**—The text of the resolution is as follows:

WHEREAS, The Principles of Medical Ethics have antedated the histories of people among whom they were developed; and,

WHEREAS, The ethical relation of the doctor and patient cannot be prescribed by civil laws; and

WHEREAS, The conservation of the patient in life and death must always remain an ethical relation; and

WHEREAS, The public has never challenged the integrity of the medical profession in this delicate situation; therefore, be it

RESOLVED, That the Principles of Ethics of the American Medical Association, adopted by the House of Delegates at Atlantic City June 4, 1912, be extended and amended to include suitable penalties for the violation of these principles:

First—That these Rules of Ethics are hereby declared to be an integral part of the Rules and Regulations, Constitutions and By-Laws, governing each component county unit and scientific section.

Second—That the penalty prescribed for the violation of these ethics shall be censure, suspension, or expulsion, as the individual governing body shall elect.

Action by the Reference Committee—The committee recommends that the resolution regarding medical ethics be adopted, and that the notification of this act be made to the C. M. A. delegates to the A. M. A. by wire.

Resolution No. 2. Research in Intestinal Parasitism—The text of the resolution is as follows:

WHEREAS, The research in intestinal parasitism now being carried on in the Department of Zoology at the University of California is of exceptional interest to scientists engaged in the study and treatment of this disease; and

WHEREAS, Its significance in many forms of pathology render this research of rare value to human life and essential to the intelligent practice of medicine; and

WHEREAS, The members of the medical profession throughout the state are fully aware of the benefit they derive from this study of intestinal parasites, appreciating the urgency of the questions which Doctor Kofoid's work is answering; therefore, be it

RESOLVED, That the California Medical Association, in annual session assembled at Yosemite Park, hereby expresses to the Board of Regents of the University of California its sense of the value of this work, its profound appreciation of the data already promulgated by Doctor Kofoid, and its belief in the vital importance of his contributions to medical science; and be it further

RESOLVED, That this association holds, in view of the highly specialized human importance of Doctor Kofoid's work, that this research is one of the most valuable in-

vestigations in modern medicine, and that we urge upon the said regents that the university continue to extend to Doctor Kofoid every facility for the continuance and enlargement of his studies in human parasitology.

Action by the Reference Committee—The committee recommends that the resolution urging the Board of Regents of the University of California to further the work of Doctor Kofoid and the Department of Zoology, be adopted.

11. Resolution on Appreciation to Yosemite Park and Curry Company—The committee voices the sentiment of the association in a vote of thanks to the Lodge for the gavel made of native manzanita presented at this meeting. It further voices the appreciation of the members for the courteous service and the kind consideration shown to all the members and their families, during this meeting in the following resolution:

RESOLVED, That the thanks of the California Medical Association be tendered the Yosemite Park and Curry Company for the very handsome gavel presented to the association; and for its many courtesies and extraordinary efforts in making the meeting a success under most trying weather conditions; and, further, that the association particularly desires to thank Mr. R. E. McCormick for the large share his unflinching efforts contributed in making the meeting a success.

12. Resolution of Appreciation to Doctor Howard A. Kelly—The Reference Committee presented the following resolution:

RESOLVED, That the California Medical Association expresses its appreciation to Doctor Howard A. Kelly of Baltimore, Maryland, for his suggestion, interest and material help in placing in Yosemite Valley a plaque to "commemorate Doctor Lafayette Houghton Bunnell, one of the first party of white men to enter the Yosemite Valley in March, 1851. He proposed the name Yosemite and was the first to proclaim its beauty and wonders to the world."

13. Resolution of Appreciation to National Park Service—The following resolution was submitted by the Reference Committee:

RESOLVED, That the thanks of the California Medical Association be tendered Mr. Stephen T. Mather, Director of National Parks, and Mr. W. B. Lewis, Superintendent of Yosemite National Park, for their many courtesies, and especially for their most helpful assistance in connection with the dedication of the Lafayette Houghton Bunnell Memorial in Yosemite National Park.

14. Resolution of Appreciation to Francis P. Farquhar—The following resolution was submitted by the Reference Committee:

RESOLVED, That the thanks of the California Medical Association be tendered Mr. Francis P. Farquhar for his most able and interesting talk at the Lafayette Houghton Bunnell Memorial exercises, and for his beautiful and instructive exhibition of Sierra scenes.

15. Yosemite Hospital—The following resolution was submitted by the Reference Committee for R. G. Dufficy of San Rafael.

WHEREAS, The hospital in the Yosemite National Park is inadequate for the present needs of the visiting tourists and traveling public; and

WHEREAS, The aforesaid hospital buildings are antiquated, out of date, unhandy and dangerous to all inmates in case of fire; and

WHEREAS, The travel into the Park is constantly increasing and the present buildings are not fit for expansion, being neither liveable in the winter and only partly comfortable in the summer; and

WHEREAS, FURTHER, There is an increasing and greater demand for a first-class medical and surgical service on the part of the visiting public from all over the United States which cannot be given in the present buildings; therefore, be it

RESOLVED, That the California Medical Association in regular session assembled exert its efforts in every possible manner on both the United States Congressmen and United States Senators in support of measures seeking an

appropriation for the building of an adequate and well-equipped hospital in the Yosemite National Park.

On motion of Harlan Shoemaker, Los Angeles, seconded by Dudley Smith, Oakland, the report of the Reference Committee, which had been read section by section, was then unanimously adopted as a whole.

Resolution of Appreciation to the Honorable George F. McNoble—On motion of Parkinson, Sacramento, unanimously seconded by the House of Delegates, it was

RESOLVED, That the sincere thanks of the California Medical Association be tendered the Honorable George F. McNoble of Stockton, President of the California Bar Association, for the extremely interesting and very valuable address made by him on Tuesday evening on the relationship of the physician and his patient.

The president called upon Mr. McNoble, who then addressed the House of Delegates.

Expression of Appreciation by the President—President MacGowan addressed the House of Delegates, briefly expressing his appreciation for the honor conferred upon him the preceding year and the pleasure derived from his presidential duties.

Presentation of the President—The president appointed Pauline Nusbaumer, Oakland, and Robert Pollock, San Diego, to escort the incoming president, Edward N. Ewer of Oakland, to the chair. Doctor Ewer was then escorted to the chair by Doctors Nusbaumer and Pollock.

Presentation of the President-Elect—The president-elect, William T. McArthur of Los Angeles, was escorted to the platform by William Duffield, Los Angeles, and Harlan Shoemaker, Los Angeles.

Reading and Adoption of Minutes—The minutes of this session were read and, there being no objection, were unanimously approved.

Adjournment—There being no further business before the House, the meeting adjourned to meet in Oakland in 1926.

SECTION ACTIVITIES OF THE C. M. A. AT THE 1925 ANNUAL SESSION

(Abstracts from Minutes of those sections whose secretaries have sent in their reports)

General Medicine Section—This section held the usual three meetings under the chairmanship of Ernest S. du Bray of San Francisco; Roy E. Thomas, Los Angeles, secretary. The scientific program was carried out very much as published in the April issue of CALIFORNIA AND WESTERN MEDICINE. Many of the papers, carefully discussed and edited, will appear during the year in CALIFORNIA AND WESTERN MEDICINE.

The chairman's address on "Comments on Body Weights in Relation to Health and Disease" will appear elsewhere in this issue, as will all other addresses of chairmen that have been received by the editor in time for publication.

At the business meeting of the section, Roy E. Thomas, Los Angeles, was elected chairman and J. Marion Read, San Francisco, secretary for the ensuing year.

General Surgery Section—This section held three meetings under the chairmanship of Wallace I. Terry, San Francisco; C. T. Sturgeon, Los Angeles, secretary. The published program was followed very closely, and a number of the papers presented, together with carefully prepared discussion, will appear in due course of time in this Journal.

At the business session of the section, T. O. Burger, San Diego, was elected chairman; E. L. Gilcreest, San Francisco, vice-chairman; J. H. Woolsey, San Francisco, secretary, and J. H. Breyer, Pasadena, assistant secretary for the ensuing year.

The following resolution was introduced, but overwhelmingly defeated:

RESOLVED, That the Surgical Section petition the Council of the California Medical Association to consider the question of appointing a committee for standardizing the preliminary qualifications of medical men in their initial attempts to do major surgery.

Pathology and Bacteriology Section—This section held three meetings under the chairmanship of Newton

Evans, Loma Linda; Roy W. Hammack, Los Angeles, secretary. Some of the papers presented before this section, in accordance with the published program, will appear in CALIFORNIA AND WESTERN MEDICINE, and others in more special journals.

At the business meeting F. R. Nuzum, Santa Barbara, was elected chairman and Roy W. Hammack, Los Angeles, was re-elected secretary.

The section discussed the advisability of continuing a separate section on pathology and bacteriology, but no action was taken.

Industrial Medicine and Surgery Section—Two meetings were held under the chairmanship of Philip H. Stephens, Los Angeles; Packard Thurber, Los Angeles, secretary. This section followed quite closely its printed program in scientific work. A number of the papers, with adequate discussion, will appear during the year in CALIFORNIA AND WESTERN MEDICINE.

At the business meeting Fred R. Fairchild, Woodland, was elected chairman and Charles E. Von Geldern of Sacramento was elected secretary for the ensuing year.

The report of the Committee of Fifteen on Industrial Medicine Problems, under the chairmanship of Sol Hyman, was discussed. Abstracts of this report will be published when released by the Council.

Radiology Section (Including Roentgenology and Radium Therapy)—The section held three sessions under the chairmanship of Ray G. Taylor, Los Angeles; Robert Newell, San Francisco, secretary. The scientific program practically as published was carried out, and some of the papers will eventually appear in this Journal, and others, no doubt, elsewhere.

At the business meeting F. H. Rodenbaugh, San Francisco, was elected chairman for the ensuing year; R. G. Van Nuys, Berkeley, vice-chairman, and C. H. Parker, Pasadena, secretary.

The section discussed plans and policies for the ensuing year, and there was a general feeling that "more of the work of the section should be called before the general medical and surgical meetings," but no definite action was taken.

Neuropsychiatry Section—Two meetings were held by this section under the chairmanship of Glenn E. Myers, Los Angeles; Joseph Catton, San Francisco, secretary. The published program was carried out, with a few minor exceptions.

At the business meeting Joseph Catton was elected chairman and Carl W. Rand, Los Angeles, secretary for the ensuing year.

A motion was made authorizing the appointment of "a neuropsychiatric council of at least five members of the section, representative of the various portions of the state. Its duties to be to act for the section during the interval between annual meetings; to study certain problems, and suggest legislative ethical and other means of dealing with them; to devote its special attention during the coming year to the subjects of commitment of the 'insane' and expert medical testimony."

Urology Section—Three meetings were held by this section under the chairmanship of Frank S. Dillingham of Los Angeles; Miley B. Wesson, San Francisco, secretary. The scientific program was carried out largely as published.

At the business meeting Miley B. Wesson, San Francisco, was elected chairman and H. A. Rosenkranz, Los Angeles, secretary for the ensuing year.

The secretary reports prompt attendance at the meetings and strict enforcement of the length of time a speaker might occupy. Two of the essayists did not appear; neither did they send any notification either before or since, and therefore, according to Rule 9, they are automatically barred from presenting a paper before this section for two years. "We limited," says the secretary, "each paper to fifteen minutes, and notified each man at the end of his fifteen minutes that he had one minute. If the audience seemed restless, he was promptly stopped at the end of the minute, whereas if the audience was very much interested we stopped him at the end of five minutes. When a man had lantern slides or was making numerous side remarks not especially connected with his subject, he was notified at the end of eleven minutes that he had four minutes, giving him an opportunity to condense and finish

his paper. Those who discussed a paper from the floor were stopped promptly at five minutes. All members present seemed to be in accord that the section meeting was one of the most successful ever held; every member had been solicited for a paper, every paper submitted was accepted; no paper was allowed to run sufficiently long to tire the audience. Doctor Dillingham was a very considerate and politic chairman and conducted the meeting so that it ran smoothly and rapidly, giving satisfaction to all present."

Eye, Ear, Nose, and Throat Section—During the three sessions of this section, under the chairmanship of Ernest W. Fleming, Los Angeles; Percival Dolman, San Francisco, secretary, the scientific program was carried out as published with a few changes, and some of the papers read will be published in CALIFORNIA AND WESTERN MEDICINE during the coming year.

"The chairman in his annual address reviewed some of the important problems which confront the eye, ear, nose, and throat practitioner of today," says the secretary. "Each one of these problems, too small in itself for review in a separate paper, was briefly discussed in a few paragraphs. The entire grouping of subjects formed a practical guide to the specialist in solving many obscure problems of his work."

At the business session W. H. Dudley, Los Angeles, was elected chairman and Percival Dolman, San Francisco, was re-elected secretary for the ensuing year.

In the absence of Chairman George K. Kress of the Legislative Committee, Secretary Dolman made a report of the activities of the committee. This report was supplemented by Otis Allen Sharpe and Arthur Hebert, who had been active in Sacramento in legislative work.

The following resolution was unanimously adopted:

BE IT RESOLVED, That this Section expresses its grateful appreciation of the magnificent support given by the League for the Conservation of Public Health to Senate Bill No. 201.

BE IT FURTHER RESOLVED, That a copy of this resolution be forwarded to the League for the Conservation of Public Health by the Section secretary.

A resolution was adopted thanking the Legislative Committee for its excellent work during the past year.

Technical Specialties Section—Both the California Association of Medical Social Workers and the California Association of Physiotherapists, who together form the present membership of the Section on Technical Specialties of the California Medical Association, held meetings. Ray Lyman Wilbur is chairman of the section and John C. Wilson, Los Angeles, secretary.

California Association of Medical Social Workers—At the scientific meeting a splendid program of five papers was presented. Most of these papers will be published during the year.

At the business meeting Edna J. Shirsper, San Francisco, was re-elected president; the position of vice-president is to be filled at the June meeting and is to be the chairman of the Southern California section. Sophie H. Mersing, San Francisco, was re-elected secretary-treasurer. Rose Steinhart, San Francisco; Alice M. Keene, San Francisco, the secretary of the Southern California section (to be elected at the June meeting), and Helen Leonard, San Francisco, were elected directors.

First steps toward amending Article III, Section 2, of the by-laws to read: "Applicants for active membership not graduated from an accredited college or school giving training in social service work shall be eligible by furnishing an equivalent satisfactory to the Advisory Council, consisting of *two years'* successful medical social work under approved medical supervision."

California Association of Physiotherapists—In the absence of Ray Lyman Wilbur, M. D., president, and John C. Wilson, M. D., secretary of the Technical Specialties Section, C. L. Lowman, M. D., Los Angeles, opened the fifth annual meeting of the California Association of Physiotherapists, member of the Section on Technical Specialties, with an address emphasizing the importance of keeping up a high standard so that this association will always be a credit to the C. M. A. The program as published was carried out with minor changes, and at the close of the evening Robert E. Ramsay, chairman of the Pediatric Section, gave a short talk

on his growing interest in physiotherapy and how his appreciation of its value had increased.

The following officers were elected for the coming year: Beulah Rader, San Francisco, president; Florence Burrell, Oakland, vice-president; Mabel Penfield, San Francisco, secretary-treasurer. Hazel Furscott, Beret Stenwig, and Margaret Blake were elected as members of the Executive Committee.

Pacific Coast Association of Anesthetists—This association held its fourth joint meeting with the Section on Anesthesiology of the C. M. A., Caroline B. Palmer, San Francisco, president, and Eleanor Seymour, Los Angeles, secretary. After a very successful scientific meeting, a business session was held, at which R. F. Hastreiter of Los Angeles was elected president, Louise Oldenbourg, Berkeley, vice-president, and Eleanor Seymour, secretary.

The following resolutions were adopted:

1. **RESOLVED**, That an expression of sincere appreciation be sent to the California Medical Association for the many courtesies so graciously extended by its efficient officers to the Pacific Coast Association of Anesthetists.

2. **RESOLVED**, That an expression of appreciation be forwarded to the secretary of the Los Angeles County Medical Association for courtesy in publishing our announcement and program in the County Bulletin.

3. **RESOLVED**, That a return wire of acknowledgment and appreciation be sent to Dr. F. H. McMechan, including greetings to the Congress of Anesthetists in Atlantic City.

4. **RESOLVED**, That an expression of regret be sent to Dr. Mary E. Botsford for her unavoidable absence.

5. **RESOLVED**, That we commend the recent ruling made by the Council on Medical Education and Hospitals of the A. M. A., to the effect that in all teaching hospitals proper equipment and facilities be provided for the instruction of interns in anesthesiology and that such instruction be given by staff members who are graduate physicians proficient in this special field.

6. **RESOLVED**, That this Association reiterates its stand deploring the employment of nurse and lay anesthetists, and endorses the attitude of the Council on Medical Education and Hospitals of the A. M. A., favoring only physician anesthetists.

7. **RESOLVED**, That we urge that all hospitals and anesthetists keep systematic records of all anesthetics administered.

8. **RESOLVED**, That a demand be made of manufacturers and hospitals to provide pure and fresh anesthetic agents at all times.

CONSTITUTION OF THE C. M. A.

First of two required publications of proposed amendments, to be voted upon by the House of Delegates 1926 session.

Amend the Constitution, Article III, Sections 1, 2, 3, 4 and 5, to read as follows:

ARTICLE III

MEMBERS AND GUESTS

Section 1. **Members**—The members of the association are the members of the component county societies and include all the active, associate and affiliate members thereof. Every member of the California Medical Association (hereafter elected) must hold the degree of Doctor of Medicine from an institution of learning accredited at the time of conferring such degree by the American Medical Association, and must be elected to membership by the component county society of the county wherein he resides, and pay all dues to the secretary of his county society.

Section 2. **Active Members**—Active members shall be elected from those Doctors of Medicine licensed to practice medicine and surgery in the state of California, who in the judgment of the component county society of the county of residence thereof, are deemed of such ethical integrity as is required for such membership. (Except if he lives on or near a county line a member may, with the previous written consent of the county of his residence,

join the society of the county most convenient for him to attend, and such adjoining county shall be included in the term "county of residence" as herein used.)

Section 3. **Associate Members**—Associate members shall be elected from those Doctors of Medicine engaged in teaching or research work or holding position in federal service or otherwise, who are not licensed to practice medicine and surgery in the state of California and hence are ineligible to active membership. These members shall have all the rights and privileges of active members, except the right to vote or hold office. Their dues to the State Association shall be one-half the dues of active members, and their dues to their county society shall be fixed by such county society.

Section 4. **Affiliate Members**—Affiliate members shall be elected from those Doctors of Medicine eligible for active membership, but who are, for any reason satisfactory to the county society and the council of the State Association, entitled to special consideration. These members shall have all the rights and privileges of other members, except the right to vote or hold office. Their dues to the State Association shall be \$1 per year, and their dues to their county society shall be fixed by such county society.

Section 5. **Honorary Members**—Honorary members of the California Medical Association may be elected by the House of Delegates.

Amend the Constitution, Article VI, Section 4, to read as follows:

ARTICLE VI

OFFICERS

Section 4. No delegate during his term of service as delegate shall be eligible to any office named in Section 1, except that of Councilor, and no person shall be elected President, President-Elect, Vice-President and Councilor who has not been a member of the association for two years preceding his election. Every delegate and alternate to the House of Delegates of the California Medical Association must have been a member of the association for one year prior to his election.

Amend By-Laws, Chapter I, Section 1, to read as follows:

BY-LAWS

CHAPTER I

Section 1. All members of county societies—active, associate and affiliate—shall by virtue of such membership hold corresponding membership in the California Medical Association upon certification by the secretary of the county society of such membership and receipt by the secretary of this association of the assessment for the fiscal year.

Amend the By-Laws, Chapter I, by adding a new section to be numbered 5, reading as follows:

Section 5. A member who changes his residence from the county through whose society he holds membership in this association to another county in which there is a county society, is eligible to membership in the component county society of his new residence on the presentation of a transfer card, and an official statement that his dues have been paid in full in the society in which he holds membership; provided that no evidence which would otherwise disqualify him for membership arise. He shall forfeit his membership in this association one year after change of location unless he becomes a member of the society of the county to which he has moved. Any member who has heretofore changed his residence as aforesaid shall have one year after the date of the adoption hereof to comply with the provisions of this section.

Amend the By-Laws, Chapter VII, Sections 4 and 14, to read as follows:

CHAPTER VII

Section 4. Each county society shall judge the qualifications of its members. However, as such societies are integral parts of this association and all the basis of membership in the American Medical Association, it is necessary that the qualifications meet the minimum requirements of the state and national organizations. These

minimum requirements are that, to be eligible for election as an active or affiliate member, the applicant must hold the degree of Doctor of Medicine from an institution of learning accredited at the time of conferring such degree by the American Medical Association, and must be licensed to practice medicine and surgery in the state of California. Every associate member must hold the degree of Doctor of Medicine from an institution of learning accredited at the time of conferring such degree by the American Medical Association, and must not be licensed to practice medicine and surgery in California and hence be ineligible to active membership. A member must not practice or claim to practice or lend his support, co-operation or in any other way endorse any exclusive system of medicine or any person practicing the same. He shall be honorable and ethical in his conduct and shall subscribe to the principles of medical ethics of the American Medical Association, and shall recognize the council of this association as the proper authority to interpret any doubtful points in ethics. Every applicant for membership in a county society shall fill out and sign in duplicate the application blanks provided by the society which prescribe the necessary qualifications for membership. One copy of each such application shall be promptly forwarded to the office of this association.

Section 14. Any county society may, in its discretion, elect active, associate, and affiliate members under and pursuant to the provisions of Article III of this Constitution. Any county society may also elect honorary members of its own society, but such honorary members shall not thereby be honorary members of this association.

ALAMEDA COUNTY

Alameda County Medical Association (reported by Pauline S. Nusbaumer, secretary)—The meeting of the association was held Monday evening, May 11, President Mehrmann in the chair.

A. A. Bird reported a case of megacolon in a boy 3 years of age, with exhibition of patient and lantern slides.

M. L. Emerson reported a case of obstruction of the bowel, with roentgenological studies.

The following program was then presented by the staff of Alameda County Hospital:

"Demonstrations of Pathological Specimens," by Gertrude Moore and N. A. Cary.

J. W. Calkins demonstrated with lantern slides and a model the operation for strabismus with modified Calkins' muscle folder. By means of this instrument, a simple method of shortening any of the external muscles of the eye is possible. The amount of shortening can be accurately graduated. The muscle is not cut, but is folded about the hairpin-shaped portion of the instrument one or more times as required to correct the deviation. The placing of the suture is simple, accurate, without danger of slipping or cutting through the sutures. Hayward G. Thomas opened the discussion of this paper.

E. W. Goodman's paper was a "Case of Spinal Cord Lesion Illustrating Advantages of Puncture of Cisterna Magna." Following a description of the technique of puncture of the cisterna magna and a resumé of the indications for this procedure, the doctor discussed the comparative values of the injection of lipiodol into the cisterna magna and of the study of different conditions of and chemistry in the fluid in the cisterna magna and the lumbar subarachnoid space. Two cases were then cited in which these maneuvers were carried out; in the first one they aided in the diagnosis of a neoplasm within the spinal canal which developed with most unusual rapidity, and in the second the level of a nervous block, due to a strong fibrous band following meningitis four years ago, was definitely shown by the obstruction to the downward passage of the lipiodol. The discussion of this paper was opened by J. E. Royer.

D. N. Richards presented a "Case of Hirschsprung's Disease Improving Under Surgical Treatment" in a boy 12 years of age. The patient was first admitted to the Alameda County Hospital March 6, 1923, complaining of abdominal distension since birth and difficulty in moving bowels. X-ray examination of colon by means of barium enemas showed an enormously dilated large intestine.

Exercise and cleansing enemas were given, and the boy was discharged. Second admission, August, 1924. Condition worse than before. Exploratory operation, August 11, 1924. Unable to outline the length of the tumor, so a simple colostomy was done. Patient sent home and readmitted October 27, 1924. Colostomy had closed. Numerous x-rays were taken to demonstrate the exact location of the dilatation, and it was found to be upper rectum and sigmoid. It had improved a great deal under this treatment. Second operation, December 6, 1924. Complete exploratory, demonstrating great hypertrophy of the intestinal wall. Loop of descending colon above dilatation was brought out and stitched to itself, according to Mikulicz's technique; colostomy established. Last x-ray picture was on April, 1925, and showed a barium fecalith in dilated portion of the intestine. Colostomy functioning well, and boy greatly improved. C. L. McVey opened the discussion.

Among other things in his paper, "Insanity as a Defense for Crime," C. W. Mack said: "It is a healthy sign that the medical profession is taking an interest in public welfare work as never before, and in doing so they cannot help but become involved in the study of individuals handicapped by mental disabilities and behavioristic problems. Psychiatry is an integral part of medicine, and its roots should be firmly grounded in orthodox practice. Psychiatry can do a great deal to help in the forward movement by contributing a study of psychopathic personalities in those afflicted with actual mental disease. A certain amount of disapprobation has been placed upon psychiatry of late because of spectacular trials that are so gruesomely represented in the newspapers—one recently in San Francisco and one in Chicago. It is not desired to take up the time of this discussion by condemning the men whose names receive so much prominence or to put forth a defense of psychiatry, as none is needed. It might be timely, however, to point out that lawyers may disagree in court without incurring any disrepute, but when doctors disagree the public naturally thinks that one side or other is falsifying for the sake of monetary profit. No psychiatrist wishes to go into court and, undoubtedly, psychiatrists as a whole have just as much honesty as any other branch of the medical profession. There is no thought in the minds of psychiatrists to secure freedom from punishment for criminals, but on the contrary they are less sentimental than the public at large. Modern psychiatry contends that there is a large element of feeble-mindedness or mental disease which accounts for a large share of the criminality. This is indicated by the fact that 60 per cent of prisoners examined show mental abnormalities which are largely responsible for the criminal tendencies. It is also worthy of note that 66 per cent of prisoners are recidivists. The present penal system is not diminishing the enormous wave of crime. The homicides in the United States in one year were 9500, whereas in Great Britain during the same period there were only sixty-three. The number of the executions out of the 9500 was only 114. In view of the fact that many criminals must be such because of their mental abnormality, they should remain in custody in a hospital throughout their entire life if necessary, or until such time as they are not a further menace to society, rather than be sentenced for a few months or years to a prison and then released. In other words, if certain types of criminals are, upon examination, found to be in such a mental condition that reformation is impossible, permanent segregation from society is what psychiatrists advocate, and they are not busying themselves in an effort to secure the acquittal of these criminals in court. The present position of doctors as experts in court is almost untenable. The new law recently adopted in Massachusetts would make it possible for physicians to be of some use to courts in handling delinquent individuals. This law makes it mandatory upon the clerk of the court where a prisoner is to be tried to notify the State Department of Mental Diseases, which department, in turn, appoints a board of examiners to determine the mental condition of the prisoner. This commission is given the larger duty also of discovering the presence or absence of any mental disease or mental defect and does not confine itself to a statement of whether or not the individual is sane or insane. This report is filed with the clerk of the court and is accessible to both the prosecution and the defense. There seems to be no

doubt but what the creation of similar legal machinery in this state would be much to our credit."

Others taking part in the discussions of these papers were Roderick O'Connor, O. D. Hamlin, R. G. Graham, and E. N. Ewer.

✽

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The regular meeting of the Contra Costa County Medical Society was held Thursday evening, May 28, at the Abbott Emergency Hospital, Richmond. Burt S. Stevens of San Francisco spoke on diseases of the pelvis. This was in the nature of a talk fest, bringing out situations we have to meet every day, and the management of which demands much diversity of opinion. Stevens showed that he is in possession of a vast amount of experience in diagnosis and treatment of pelvic diseases.

The attendance was small, due to the change of date for the meeting, and, therefore, no business was discussed.

✽

FRESNO COUNTY

Fresno County Medical Society (reported by T. Floyd Bell, secretary)—The monthly luncheon of the Fresno County Medical Society was held at the Fresno Commercial Club May 23, with twenty-six members and two visitors present. Members—Drs. Aller, Anderson, Bell, Barr, Cross, Dahlgren, Dau, Ellsworth, James, Jorgensen, Kjaerbye, G. L. Long, Manson, Miller, Montgomery, Mitchell, Newton, Pettis, Pomeroy, Schottstaedt, Sciaroni, Sheldon, Stein, Tillman, Tupper, and J. R. Walker.

Lee S. Seward, director of the Tri-County Tuberculosis Hospital at Ahwahnee, presented an interesting and very instructive paper on "Errors in Diagnosis and Therapeutics in Tuberculosis." He said that the errors in diagnosis were largely due to careless physical examination. Many of the cases with cough were diagnosed as "heart cough" or asthma. Many of the old chronic cases of pulmonary tuberculosis take care of their infection pretty well, except for chronic cough, etc., but are a source of infection in the spread of the disease to others, especially children. The x-ray is a great help in diagnosis, but only an aid, and one cannot differentiate between an active and a quiescent lesion by the x-ray. The proper treatment for pulmonary tuberculosis is that type of treatment which promotes rest for the respiratory apparatus. The advice sometimes given to tuberculous patients to go to the mountains and "rough it" is very bad treatment. Likewise the undue forcing of foods is undesirable. Climate does not make as much difference as does the kind of treatment carried out, except that patients probably do better in that climate where they are most comfortable.

Numerous questions were asked, especially since Fresno County is contemplating additional means of taking care of its tuberculous patients. Seward gave a brief history of the Ahwahnee Hospital. He said that the cost per day per bed there was \$2.79. This was about \$1.36 more than the cost for such patients as taken care of at the various county hospitals. This additional cost was entirely for service rendered, no expense being spared to take care of cases at Ahwahnee. He said that Fresno County should have two tuberculous hospitals—one in the foothills for convalescents and a preventorium for children, and one in the valley for hopeless and advanced cases. He outlined a big program if the tuberculosis problem is to be handled properly.

Cross moved, Schottstaedt seconded, that a committee be appointed to investigate the advisability of erecting a tuberculosis sanitarium for Fresno County in the valley or foothills, and report by June 2. Carried. Ellsworth, Tupper, and Mitchell appointed.

The regular meeting of the Fresno County Medical Society was held June 2 at the nurses' home of the General Hospital. There were twenty-two members and six visitors present. Members—Aller, Anderson, Bell, Couey, Cross, Dau, Ellsworth, Ingram, Kjaerbye, Larson, Miller, Montgomery, Mitchell, Nedry, Nider, Pettis, Schottstaedt, Sheldon, Tillman, Tupper, J. R. Walker, and Wiese. Visitors—Dr. Tranter and members of resident staff of the General Hospital.

Dr. Ellsworth reported for the committee recently ap-

pointed to report on the proposed tuberculosis hospital for Fresno County. He stated that, due to lack of time, the committee wished simply to indorse the proposition of building a tuberculosis hospital, but that the matter of possible and desirable locations for the institution should be left for future consideration. He said that the committee wished to make a more detailed report later in the summer. The report was accepted.

President Anderson reported on several matters which came before the State Council recently at the Yosemite meeting.

Charles L. Tranter of San Francisco presented a paper on "Traumatic Surgery of the Nervous System," illustrated by lantern slides. Neurological surgery may be divided into two large classes: (1) Traumatic surgery, and (2) tumors of the central nervous system and neuralgias. The former are more common and are the subject of the discussion.

Tranter emphasized the cardinal and auxiliary symptoms in cases of head injury, and pointed out those cases which recovered without operation, those in which operation was imperative, and those which usually died anyway.

The methods of procedure, i. e., operations, as far as the brain is concerned, are three: (1) Repair of skull defects; (2) subtemporal decompression; and (3) removal of broken pieces of skull. He presented several cases of repair of skull defects with associated brain conditions, such patients either having epilepsy, or some other condition being present, such as aphasia. He showed slides demonstrating the use of the osteo-periosteal graft. The use of foreign substances to close defects is a thing of the past. He spoke of the importance of Cushing's method of subtemporal decompression in cases of increased intracranial pressure. He also said that most authorities now believe lumbar puncture is a harmless and valuable procedure in such cases, and should be tried before decompression is done.

Surgery of the peripheral nerves may comprise any one of five procedures: (1) Neurolysis, or the removal of scar tissue; (2) simple suture; (3) transplantation of nerve and suture; (4) resection of a partial neuroma; and (5) amputation of neuromata. Dr. Tranter discussed these different methods; also the technique of suturing, resection and stretching of nerves.

✽

MARIN COUNTY

Marin County Medical Society (reported by J. H. Kuser, secretary)—The May meeting was held at W. F. Jones' office. H. O. Hund, W. F. Jones, C. W. Clark, O. W. Jones, and J. H. Kuser present. The delegate to the State Association being absent, the purpose of the meeting—a report by said delegate, Dr. Rafael Dufficy—could not be carried out.

✽

SACRAMENTO COUNTY

The Sacramento Society for Medical Improvement (according to the report of E. S. Babcock, secretary pro tem.) met at the Sacramento Hotel, May 26; thirty members present. The minutes of the previous meeting were read and approved.

Charles E. Schoff reported a case of psoriasis in a Chinaman.

The paper of the evening on "Fractures, Their Diagnosis and Treatment" was read by Frank P. Brendel. A large number of lantern slides showing most of the common fractures and many uncommon types, with both correct and faulty reduction, and proper and improper plating, were shown to illustrate his excellent paper.

Royal de R. Baronides and J. W. Wilson were elected to membership in the society.

Considerable time was given to reports of the state convention, started by Delegate C. B. Jones. A communication from Secretary Bert Thomas, further reporting the convention, was read by P. W. Christman. Dr. Parkinson, Councilor Eighth District, gave a resumé of the following subjects: Optional medical defense; permanent location for annual meetings; conflicts in schedule of section meetings; certification of delegates and alternates; Officers Reserve Corps; on choosing the site for the Bunnell Memorial; income tax, as related to physicians.

SAN FRANCISCO COUNTY

St. Luke's Hospital Notes—The regular meeting of St. Luke's Hospital Clinical Club was held Thursday, May 14, J. Marion Read being the speaker of the day, and taking for his subject, "Prognosis and Choice of Treatment in Grave's Disease," his conclusions being based on an intensive study of one hundred cases seen by him during the past six years. Points brought out in discussion were: That diagnosis of this disease is easy, since basal metabolic determinations are obtainable almost anywhere, but since its etiology is still unknown, treatment still rests on an empiric basis; that it is about eight times more frequent in females than in males; that it has many atypical forms; that it often tends toward spontaneous recovery, which makes the valuation of therapeutic measures exceedingly difficult; that it is prone to run a cyclic course with periods of remissions and recrudescences; that its incidence is greater in goiter districts; and that there seems to be an irreducible minimum of mortality.

From a prognostic point of view, one may conclude that some patients will get well (the form of therapy employed receiving credit therefor); some will die, in spite of all therapy and some because of it; and there is a group in which therapeutic efforts may affect the ultimate outcome of the case to a slight extent. The metabolic rate is the best quantitative measure of the degree in which the condition exists. It is not possible to predict from the rate, however, the probable time limit of the disease.

This Clinical Club met again on June 11. The feature of the day's program was the practical demonstration by R. L. Dresel of an improved fracture bed. Dr. Johnson, superintendent of the hospital, in his preliminary remarks stated that for the past two years the hospital had been having a great deal of trouble with fracture beds; that for several months Dr. Dresel had been working on a standardization of fracture beds and splints, and that today he was prepared to demonstrate a bed that had been worked out under his supervision.

Dresel briefly outlined some of the difficulties encountered with the old fracture beds—they would not go into the elevators; they occasionally fell down while in use; they were expensive, from the standpoint of both equipment and labor; they had no permanent superstructure, whatever constructed when necessity arose being of a makeshift nature. He proceeded to demonstrate the strength and durability of the improved bed. He showed that it can be raised and lowered without disturbing traction; that it has a superstructure that will stay, and that it is not only a fracture bed but a foundation for many kinds of care. He went on to say that there had also been much difficulty with splints; they had been of all sizes and materials. Now they had been standardized and made to fit the bed; there were lengths to fit the children's beds, as well as the adults'. He closed his remarks with a request for criticism and for any suggestions for improvement that his audience desired to make.

St. Joseph's Hospital Notes—St. Joseph's Hospital staff, San Francisco, met June 10, A. S. Musante presiding, and heard Edmund Butler, chief emergency surgeon, speak on "Surgical First Aid," abstracted below:

"In a recent visit East the emergency service of many cities was observed, many of these being but the outpatient departments of the district hospitals, instead of independent departments. San Francisco ranks high in economy, promptness, and efficiency. We had 38,500 admissions last year, of which 29,500 were surgical.

Routine fundamentals for wounds are a careful exploration, mechanical cleansing without abuse of tissue, the removal of devitalized soft parts that are contaminated, judicious drainage, and the proper use of antiseptics, sutures and wet or dry dressings. Most are iodized and dressed with equal parts of glycerin and 95 per cent alcohol. Scalp wounds are inspected for foreign material. If the pericranium is torn, the skull is inspected for fracture, but the wound is not enlarged. In face wounds exact approximation, without wrinkling and angling, is obtained with sutures. Eyelid wounds must be handled gently and nicely approximated, to avoid bad scars. Fine round needles and horse hair and silk sutures are used and drainage with rubber tissue favored. In neck wounds, often suicidal, the mucous membrane of the pharynx is sutured with catgut, muscles with chromic and skin joined

so as not to impede drainage, which is placed in the angles and midline. Stab, gunshot and crushing wounds of the chest are generally treated expectantly. Primary shock is great, but the prognosis is good. Blood is not aspirated early, as the compressed lung reduces movement and favors clotting; if allowed to expand, secondary bleeding may occur. All openings in the pleural cavities are closed at once—at first with a sterile towel wrung out of sterile salt solution and then with figure-of-eight silk worm sutures, including muscles, fascia and skin. Abdominal stab, gunshot and contused wounds require intervention. Ruptured spleen is misleading, as primary shock and low blood pressure allow clotting to occur in the tear, but in six to ten hours the blood pressure increases, the clots are dislodged and secondary bleeding ensues, accompanied by slight abdominal pain and distention and polymorphonuclear leucocytosis. Leucocytosis occurs in all bleedings into serous cavities and soft parts, and may reach 50,000. Intraperitoneal rupture of the bladder does not cause alarming symptoms, and the pain is often ascribed to contusions of the abdominal wall, enteritis or, in females, to salpingitis. Intervention, if delayed, has a high mortality.

Injuries to limbs make up most of emergencies. Simple fractures are reduced as completely as possible without anesthetic and immobilized with cardboard. In compound fractures the skin is shaved and prepared to wound and the end of bones, if protruding, cleansed and iodized. Drains, glycerin and alcohol compresses and immobilization are utilized. In lacerated wounds, few sutures, free drainage and above compresses are used. Cut tendons are sutured at once, or if patient has a physician, latter is notified at once, the wound shaved, iodized, compressed, and splinted. Burns are treated with antipyraxol."

Dr. Alex Keenan praised the fairness of Dr. Butler's service towards doctors and the excellence and immensity of its growth.

Dr. Samuel H. Hurwitz spoke on the "Modern Treatment of Asthma," the following notes being stressed:

"There are two main causes of asthma—idiosyncrasy to certain substances (proteids) and infections. Real asthma is distinguished from the dyspnoea of cardiac, renal, and other diseases. The foreign proteid substances can be taken in by such methods as ingestion, inhalation or absorption, and produce asthma, hives, and eczema. Certain foods—even essential ones—and emanations from domestic and other animals are causes of trouble. The diagnosis can be made by rubbing into the skin or injecting (too sensitive) suspected substances or their extracts to note reaction. If a wheal, itching or redness develops, it is indicative of a positive reaction. The history may disclose hereditary manifestations in early life. The onset may be noted after certain occupations (hostlers, bakers, etc.) are entered.

The prognosis for desensitization is good if the asthma is not of too long standing. Some metabolic factor, like dysfunction of ductless glands, may need correction and diet, and other hygienic measures may be needed.

The infectious group of asthmas may be due to respiratory tract origin, especially the sinuses, gall-bladder, and occasionally the kidneys. Certain groups are often recognized, like that of children after many respiratory diseases, that after influenza and that following a long history of bronchitis. The infectious type of asthma often does well. Treatment is based on the bacteriology disclosed by a careful sputum culture. Vaccines from the organisms found are used; if several, inject each one and those producing the most reaction will generally clear up the condition. The autogenous vaccines are best. Fifty million are injected every five to seven days, and even larger doses are then used. Surgical aids in removal of pathology should be considered. Climate makes but little difference. Both desensitization and vaccine therapy are used if indicated.

In the attacks of asthma, adrenalin and morphine sulphate are best."

Drs. Philip Collischonn and F. A. Lowe presented case histories of purulent bronchitis and pre-eclamptogenic toxemia, respectively.

SANTA BARBARA COUNTY

The American Association for Medical Progress, Inc.—The Santa Barbara branch of this organization was addressed by Mr. Benjamin C. Gruenberg, managing director of the American Association for Medical Progress of New York, and Walter C. Alvarez, M. D., of San Francisco.

Many of our most prominent citizens have taken memberships in this organization of laymen, whose object is to disseminate as widely as possible authentic information regarding the fundamentals of modern medicine, including the methods of research by means of which reliable knowledge is obtained as to cause, prevention and cure of disease.

"Full use of our best scientific knowledge," says President Coleman, "is possible only with the support and co-operation of the public, but such co-operation depends upon an appreciation of what scientific medicine and research mean. Ignorance, apathy and superstition are a menace to medical progress and to the health of the people, not only in actual opposition to scientific methods, but in a failure to understand the scientific attitude. This can be remedied by continuous education, and our people may thus be guarded against quacks and charlatans."

Mr. George E. Coleman is president; Mr. F. F. Peabody, chairman Lay Advisory Board; and Miss Pauline M. Finley, secretary-treasurer of the Santa Barbara County branch.

SONOMA COUNTY

Sonoma County Medical Society (reported by G. A. Hunt, secretary)—A joint meeting of the Sonoma, Mendocino, and Lake County Medical Societies was held in the hospital of W. C. Shipley in Cloverdale, Thursday, May 14.

J. H. McLeod of Santa Rosa addressed the meeting on the "Nasal Accessory Sinuses." Many lantern slides were shown which helped to make Dr. McLeod's talk interesting and instructive to the general practitioner, as well as to the specialist. A general discussion followed.

CHANGES IN MEMBERSHIP

New Members—Alameda County—E. J. Finnerty, G. M. Kennedy, Oscar K. Mohs, Abilio Reis, Oakland; J. Elliott Royer, Berkeley.

Kern County—Kenneth M. Cook, Taft.

Marin County—Homer E. Marston, San Quentin.

Orange County—William C. Bruff, Anaheim.

San Francisco County—James F. Runner, Frederick Ebersson, George F. Oviedo, William A. Blanck, San Francisco.

Santa Clara County—Hugo Schmitt, Palo Alto.

Solano County—Durward B. Park, R. I. Longabaugh, Vallejo.

Sonoma County—James C. Johnstone.

Deaths—Bronson, Edith. Died at Yosemite National Park, May 26, 1925, age 38. Graduate of Johns Hopkins Medical School, Maryland, 1913. Licensed in California in 1913. Doctor Bronson was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Cline, John Welby. Died at El Monte, May 14, 1925, age 57. Graduate of the University of Colorado School of Medicine, Boulder, Denver, 1896. Licensed in California in 1913. Doctor Cline was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Horel, Francis R. Died at Arcata in April, 1925, age 74. Graduate of Rush Medical College, Illinois, 1885. Licensed in California in 1891. Doctor Horel was a member of the Humboldt County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Obituary

EDITH BRONSON

The recent death of Doctor Edith Bronson, Assistant Professor in the Department of Pediatrics of the University of California Medical School, takes from the medical profession of California a woman with exceptional training and brilliant attainments in the field of research. Born and educated in Vermont's schools and academy, she took her A. B. degree from Syracuse University and entered the Medical School, where although a classical student, she won her master's degree in zoology and chemistry. Her scientific interest in research determined her entrance at Johns Hopkins University, and in 1913 she won her M. D. degree there. Her first internship was in the Children's Hospital in San Francisco, 1913-1914. Her second internship was in the New York City Children's Hospital in 1914. With the war came that call to go overseas and serve with the countries already bearing the burden. Doctor Bronson went first to the Hospital for Sick Children in Edinburgh and during 1915-1916 served as a resident. While there the association with Dr. John Thomson and Dr. J. S. Fowler enriched and broadened her scientific work and earned for her the friendship and interest of these leaders in the field of modern pediatrics. 1916-1917 found Doctor Bronson a resident in the Children's Hospital at Paddington Green, London, and the following year a resident in the Children's Hospital at Pendlebury, Manchester. The war children with their bitter needs flowing from the great munition plants in the heart of industrial England drew from Doctor Bronson her finest and best. She worked with an intensity that left its mark upon her fine sensitive spirit. In 1918 and 1919 she became one of the outpatient physicians in the famous Children's Hospital in Great Ormond street, London, where again her association with such leaders as Sir James Mackenzie, Dr. Leonard Guthrie, and Dr. G. Sutherland brought fresh devotion to her work and won for her the respect and admiration of her chiefs. Late in 1919 Doctor Bronson returned to her work at the University of California Hospital and the Children's Hospital, where the brilliancy of her mind, the fineness of her spirit, the true discriminating sense of values in her work brought instant recognition. The study of heart conditions has been her major interest for a number of years and her contribution to the subject had already been noteworthy. "Nodules," "Fragilitas Ossium," "Aneurysms in Childhood," "Influenza Associated with Jaundice," "Physiotherapy in Heart Disease," are some of the published articles that firmly establish Doctor Bronson's place in research. Her death at the early age of 38 leaves the medical profession in California poorer and takes from the group of women physicians in Northern California one who brought to her work an enviable training and distinction.

Endameba Coli—Sixteen cases in which endameba coli (councilmania type) was found by J. H. Hall and A. C. Reed, San Francisco (Journal A. M. A., June 20, 1925), are here reviewed as to clinical history. The complaints and symptoms were more or less variable and indefinite, in many comprising a picture usually described as neurasthenia. The most frequent reports were of epigastric discomfort, flatulence and constipation, not accounted for by the presence of any discoverable organic lesion of the digestive tract. All patients had, as a routine, physical examination, history, blood count, Wassermann test, urinalysis, gastrointestinal roentgenograms, stool analysis and, frequently, gastric content analysis. Other group symptoms were even less definite, as general debility, fatigue, vertigo, neuralgic pains and physical discomfort. Most of these patients were middle-aged men. A routine treatment was used in this group similar to that employed against *E. histolytica*.

MURPHY MEMORIAL HOSPITAL AT WHITTIER AGAIN

The astounding developments growing out of the giving, building, and maintaining of the Murphy Memorial Hospital at Whittier, California, by Colonel Murphy have been commented upon in *CALIFORNIA AND WESTERN MEDICINE* and "Better Health," several times, and these comments have been widely reproduced in both scientific and more public literature. The outstanding facts are that Colonel Murphy had designed and built an unusually beautiful hospital at Whittier as a memorial to his father. Considerably more than a third of a million dollars was spent in construction alone. At the same time the benefactor made provision for doubling the size of the hospital later on again at his expense, and included a bequest in his will of \$200,000 as an endowment in perpetuity to take care of citizens of the community who would not be able to pay the cost of good hospital service.

Colonel Murphy then entered into negotiations with the authorities of the city of Whittier by which he donated the hospital to the municipality under certain conditions. The outstanding feature of these conditions was, that the hospital was always to be maintained as a "Class A" hospital. This document was duly and as legally executed as it is possible to do, in dealing with our small town governments. The trustees, in carrying out the requirements for a first-class hospital insisted, as is required by the American Medical Association, American College of Surgeons, and all other good medical organizations, that none but educated doctors of medicine be permitted to practice in the hospital. This procedure aroused the ire of the many classes of cultists and those who do not believe in medicine at all as well, and through the usual legal machinery they brought the question to a vote of the people of the municipality. The cultists, aided, we are sorry to say, by a few licensed physicians, succeeded in carrying the election, the result of which was to treat the benefactor, who is still living, with discourtesy, to express it mildly, and to treat the official legal paper of the municipality as a proverbial "scrap of paper." This action opened the hospital to all and sundry.

The next stage in the development of this debacle was that Colonel Murphy, through his attorneys, made preparations to enter suit to declare the original trust void because of abrogation of contract on the part of the city, and demanded the return of his property to his estate. In the meantime, Colonel Murphy's health continued to fail and the lawsuit was given up and has now been withdrawn, and with that withdrawal the benefactor has deleted the \$200,000 endowment which had been included in his will, and has otherwise amputated himself from the situation in the following letter:

"May 23, 1925.

Board of Trustees of the City of Whittier,
Whittier, California.

Gentlemen—Receipt is acknowledged of your letter of May 18. I cannot appreciate or agree with your position. I am addressing this final letter to you in order that the records of the city may clearly show that I do not concur with or acquiesce in the statements contained in your letter, or the manner in which you propose to operate the Murphy Memorial Hospital.

Your attitude absolutely ignores the condition in the original deed of gift that the hospital should be always maintained as a Class A hospital: namely, as a standardized hospital according to the high standards of the American Medical Association and the American College of Surgeons. It also ignores the absolute promise of the city (contained in the resolution of acceptance by the Board of Trustees of the city of my offer to build the new wing) that the hospital should always be maintained according to the high standards then established, which the records of the hospital show were exactly those of a Class A hospital, as above defined. I am convinced that the city is both morally and legally obligated to maintain these standards, and, had my health permitted me to continue my case against the city until it could have been tried upon its merits, I feel confident that the court would have so decided.

Common honesty and fair dealing require the city to

maintain the hospital according to these standards, even though the city were not already legally bound to do so. Such being the condition of the gift, I do not believe that there is any merit in your claim that the law of the state of California requires you to do anything other than to live up to the terms and conditions of the gift, which permit anyone to practice in the hospital who has the requisite educational and ethical qualifications to practice in a standardized medical and surgical hospital.

Unless the hospital is maintained as a standardized hospital (which it will not be if practitioners licensed to practice any method of healing, or who are unethical in their practice, are admitted to its staff), the reputation of the hospital will rapidly dwindle and the people of the city of Whittier will not receive the high type of modern hospital service which it should have and which I intended to give it.

It is because of the attitude of the present officials of your board and of the present board of hospital trustees in lowering the standards of the hospital and in ignoring the city's agreement with me that I have lost my former keen interest in the hospital. It was because of such attitude, and because of my recent poor health and an expected trip to my home in Charleston, West Virginia, that I dismissed the suit against the city, without prejudice to my rights as donor. Because of such attitude I feel that not only the money invested by me in the hospital is a loss, but that the hospital will no longer be the kind of a memorial to my beloved father and mother which I intended it to be. So I have caused their pictures to be removed from the hospital.

My views have been so clearly set forth in this and my prior communications that there ought not to be the slightest misunderstanding as to my position, and as far as I am concerned, please let this letter finally close the matter. For these reasons, and because of my health, I do not desire any further discussion of the subject either by letter or interview.

Yours respectfully,

(Signed) SIMON J. MURPHY, JR."

Doctor H. P. Wilson, the personal physician and the personal friend of Colonel Murphy, who took such an intense interest in advising Colonel Murphy constantly in the various steps by which he had hoped to create a fine hospital to serve a small community, in forwarding the above letter from Colonel Murphy, says: "There is a distinct element among the best people of this community who are chafing under this thing and who still hope that the hospital may be restored to its former dignified status."

Needless to say that this hospital, at one time so full of promise, will not succeed in obtaining accredited standing before medical bodies until some assurance of the right kind of stability has been pledged and practiced under this pledge for a sufficient length of time and with earnestness of purpose and that kind of municipal regard for obligations not heretofore manifested.

This matter is given thus fully because it is no longer a little local problem for a small community in California, but has reached around the world in the news columns and editorial comment as one of the outstanding shames in modern health betterment.

WESTERN BRANCH AMERICAN UROLOGICAL ASSOCIATION

This organization held a meeting in connection with the session of the California Medical Association in Yosemite. The members were notified of the adoption of the new constitution.

The officers elected for the ensuing year were George Hartman, chairman; Anders Peterson, secretary; Louis Clive Jacobs, vice-president; J. C. Negley, treasurer.

A resolution recommending the holding of a special scientific meeting in San Francisco, either in October or November of 1925, was adopted. The following papers were presented:

"Bladder Disturbances and Lesions of the Nervous System"—Leon Meyers.

"Surgery of Tumors of the Bladder"—Verne Hunt.

"Carcinoma of the Urachus"—Paul Ferrier.

Utah State Medical Association

ACQUIRING MERIT

The Orientals have a saying when a man performs a kindly act or one contributing to the welfare or comfort of a fellow-being that he "acquires merit" thereby. The thought is one worth considering in its application to the association of human beings East or West, we think, and surely the officers of the State Association and the committee on education deserve great credit and have acquired much merit by the work done on the post-graduate course in connection with the annual state meeting in September, a full provisional schedule of which is printed in the body of these notes.

Times were when the standard of the county society or the state society, with rare exceptions, was that of the best informed man in the county or state. But times change. Today the possible standard is limited only by the knowledge of the profession at large. Modern means of communication and transportation have largely militated to this end. Too, there is a friendly, co-operative spirit growing up within our own ranks—a sincere desire to disseminate knowledge more than ever before.

There is, however, another way of acquiring merit. Enough that the committee has furnished the program—bigger, better, and more comprehensive than ever before in the history of the state. The duty now devolves upon every member of the profession within the commonwealth to avail himself of the rich mental banquet provided to his own betterment. This is bringing the university and college to his doors. The question is, shall he, will he partake? It is his moral duty to do so, for to him men and women and little children entrust daily their physical well-being—indeed, their lives. In the assuming of such a trust, surely no man should fail to equip himself with the best available knowledge. Does he not do so, he betrays a trust, and what true man would wish to so stultify either his profession or himself? It is to be hoped, then, that the medical men of Utah will let no avoidable consideration stand in their way in attending this course of intensive instruction—that they will hasten to arrange to be present, and that in so doing they will acquire merit for the days and months to follow. An ignorant physician is a danger to his patients—to his profession in this day and age, a disgrace. Literally, today the doctor is a soldier as much as he who wears a uniform and faces a barrage.

"If ye break faith, we shall not sleep
 Tho' poppies bloom in Flanders' fields—"

Learn, work, rest. It is the doctor's as well as the layman's life.

And surely he who seeks to learn all he may, work truly and sincerely, may best rest, when his work is

done, with a conscience clear and a knowledge that such merit as he may have acquired in the eyes of his fellows was deserved.

TROUBLESOME TENANTS

We medical men are troublesome tenants if the managements of office buildings are to be believed. We make so much elevator traffic with our patients, we make so much demand on the building service of light, heat, gas, water—in fact, everything. If we're surgeons, we have bloody dressings in containers which make the charwomen sick. If we do minor operations in our offices, we disturb the other tenants with the concomitant yells and shrieks our patients emit, or should we use an anesthetic the smell puts the stenos of the adjoining offices to sleep. Our office girls visit with other office girls (or boys) and demoralize the service in every possible way. As a matter of fact, we are a sort of gang to be tolerated and permitted to pay rent, under duress, in case the building happens to have some space it wants filled up.

Consequently, it is with a feeling of something like dazed amazement that we note two announcements affecting the medical tenant directly within the past week. First to come was the news that the C. A. Quigley building, a fourteen-story, modern office structure, to be erected in the congested district, will set aside six to eight floors for the use of "the Docs." Second is the news that, inside the year, it is proposed to erect an exclusive medical and dental building—the Medical Arts building, as now provisionally called—which will literally house nothing save the two professions. This is to be a ten-story structure, built entirely for professional needs.

"Ubinam gentium sumus!" Cicero exclaims, "Where in the world are we!" Can it be possible that we poor orphans are at last to be provided with home and shelter inside the coming few months? Yet, why not? The thing has proved successful in other cities. We feel sure that both enterprises will be appreciated and patronized by the professions in Salt Lake.

Utah Notes (reported by J. U. Giesy, associate editor)—*New Office Building*—It is announced that the C. A. Quigley building will soon be erected on Exchange Place. This will be a modern fourteen-story building in which six or eight floors are to be set aside for the needs of physicians and dentists. This is a welcome bit of news to the professions affected who for so long have felt the need of some such available space for offices designed and equipped for medical and dental needs rather than the makeshift arrangements of general office buildings for which physicians have been permitted to pay rent.

Salathiel Ewing, M. D., 1834-1925—Doctor Ewing, dean of medical men in Salt Lake, died recently of cerebral hemorrhage, at the age of 91 years. He was born in Union County, Ohio, December 24, 1834, and came to Salt Lake in 1883, where he conducted active practice until his death.

1925 Session U. M. A. Combined With Post-Graduate Week—This year the sessions of the State Medical Association will be combined with courses of graduate instruction, and the combined sessions will occupy the entire week of September 7 to 12.

Below will be found the provisional program of the post-graduate course to be held in connection with the annual meeting. We are proud to print this program. It touches the high mark of medical progress in Utah. It is

a golden opportunity knocking at the door of every sincere practitioner in the state. Read it and smile in anticipation.

"Some four years ago the Utah State Medical Association inaugurated the plan of having a week of clinics and inviting someone of eminence in the profession to conduct the same. The first two years were confined to diagnostic clinics in medicine; last year we added clinics in pediatrics and a review course in laboratory diagnosis; this year we are going further. The course will be combined with the annual meeting of the State Medical Association, and we will have an intensive week, covering the entire field. There will be papers, clinics, discussions, each day from 8 in the morning until 10 at night. Such a medical feast has never before been offered in this intermountain country. Those who will conduct this course are men of outstanding eminence in the profession. There will be work for the specialist; there will be work for the general practitioner remote from the aids of the up-to-date laboratory, x-ray, etc.; there will be work for everyone. You cannot afford to miss what will constitute practically an intensive six-day post-graduate course almost at your door.

A nominal registration fee of \$10 will be charged for the clinical course.

Date: September 7 to 12, 1925.

The following will conduct the course. A mere recital of the names is convincing proof of the excellence of the program:

Walter C. Alvarez, Professor of Research Medicine, University of California Medical School.

Joseph C. Beck, Professor of Otology, Rhinology and Laryngology, University of Illinois College of Medicine.

William F. Braasch, Professor of Urology, University of Minnesota Post-Graduate School of Medicine, Mayo Clinic.

Russell D. Carman, Professor of Roentgenology, University of Minnesota Post-Graduate School of Medicine, Mayo Clinic.

George B. Eusterman, Professor of Gastro-Enterology, University of Minnesota Post-Graduate School of Medicine, Mayo Clinic.

Alexius M. Forster, Chief of Staff, Cragmor Sanatorium for Tuberculosis.

Martin F. Engman, Professor of Dermatology, Washington University Medical School.

Carl A. Hamann, Dean and Professor of Applied Anatomy and Clinical Surgery, Western Reserve University School of Medicine.

Julius H. Hess, Professor of Pediatrics, University of Illinois College of Medicine.

Edward Jackson, Professor of Ophthalmology, University of Colorado School of Medicine.

John L. Porter, Professor of orthopedic Surgery, Northwestern University Medical School.

Ernest Sachs, Professor of Clinical Neurological Surgery, Washington University Medical School.

Final program announcing subjects will be mailed.

Your early registration is earnestly suggested.

Any further information will be cheerfully furnished."

THE ANNUAL MEETING AND POST-GRADUATE WEEK
IN OUTLINE

Monday, September 7

8 to 9
Laboratory; Blood Count; Urinalysis.

9 to 12
Papers—Dr. Eusterman, Dr. Carman, Dr. Hess.

12 to 2
Meeting—House of Delegates.

2 to 6
Papers—Dr. Hamann, Dr. Braasch, Dr. Engman.

Meeting—House of Delegates.

8 to 10
Papers—Dr. Jackson, Dr. Beck.

Tuesday, September 8

8 to 9
Laboratory; Blood Chemistry.

9 to 12
Papers—Dr. Alvarez, Dr. Calonge, Dr. Hess, Dr. Sachs.

12 to 2
Meeting—House of Delegates.

2 to 6
Papers—Dr. Porter, Dr. Forster, Dr. Sundwall, Dr. Eusterman, Dr. Carman.

8 to 10
Banquet.

Wednesday, September 9

8 to 9
Laboratory; Serology.

9 to 12
Papers—Dr. Hamann, Dr. Alvarez, Dr. Engman.

2 to 6
Papers—Dr. Jackson, Dr. Porter, Dr. Sachs, Dr. Braasch.

8 to 10
Papers—Dr. Eusterman, Dr. Carman.

Thursday, September 10

8 to 9
Laboratory; Bacteriology—Sputum Examination.

9 to 12
Clinics—Dr. Hamann, Dr. Braasch, Dr. Engman.

2 to 6
Clinics—Dr. Porter, Dr. Sachs, Dr. Beck, Dr. Hess.

8 to 10
Clinic—Dr. Alvarez.

Friday, September 11

8 to 9
Laboratory; Gastric Analysis; Feces.

9 to 12
Clinics—Dr. Hamann, Dr. Alvarez.

2 to 6
Clinics—Dr. Hess, Dr. Eusterman, Dr. Carman.

8 to 10
Clinic—Dr. Forster.

Saturday, September 12

8 to 9
Laboratory; Tissue Diagnosis.

9 to 12
Clinics—Dr. Alvarez, Dr. Hamann.

2 to 6
Clinics—Dr. Forster, Dr. Hess.

All meetings, clinics and laboratory demonstrations will be held at the University of Utah.

Luncheon will be served at the University dining-hall daily.

The papers and clinics of Drs. Jackson and Beck will be on subjects of interest to the general practitioner.

EYE, EAR, NOSE, AND THROAT SECTION

Monday, September 7

12 to 2
Luncheon.

2 to 6
Papers or Clinical Talks—Dr. Jackson, Dr. Beck.

8 to 10
Papers—Dr. Jackson, Dr. Beck.

Tuesday, September 8

9 to 12
Papers—Dr. Beck, Dr. Jackson.

12 to 2
Luncheon.

2 to 6
Papers or Clinical Talks—Dr. Jackson, Dr. Beck.

Wednesday, September 9

9 to 12
Paper—Dr. Jackson.

12 to 2
Luncheon.

2 to 6
Clinic—Dr. Jackson.

Thursday, September 10

9 to 12
Papers—Dr. Beck.

12 to 2
Luncheon.

2 to 6
Clinic—Dr. Beck.

Papers and Clinics will be at the University of Utah, unless otherwise posted.

Salt Lake County Medical Society (reported by M. M. Critchlow, secretary)—At the meeting of June 8 President Brown announced the appointment of A. A. Kerr,

chairman, and Willard Christopherson and B. E. Bonar members of the committee to investigate the Visiting Nurses' Organization. Dr. Kerr reported for the committee and recommended that the Salt Lake County Medical Society endorse the organization of the Visiting Nursing Association if it were properly managed. The report was referred to the Committee on Public Health and Legislation for their action.

T. C. Gibson reported for the Committee to Supervise Public Lectures. Fred Stauffer reported for the Building Committee. F. B. Steele reported for the Library Committee. The secretary announced that the American Medical Association auto emblems have arrived.

A special meeting was called for June 16 to hear a representative of the American Birth Control League.

A telegram from James F. Percy was read, announcing that he could address the society if they wished. An invitation was extended to Dr. Percy to talk at a special meeting.

The following men were elected delegates to the Utah State Medical Association for two years: T. A. Flood, G. F. Roberts, L. N. Ossman, John Z. Brown, J. P. Kerby, F. H. Raley, S. D. Calonge, E. D. LeCompte, and R. R. Hampton. The following were elected delegates to serve one year: S. C. Baldwin and E. L. Skidmore. The following were elected alternates: G. N. Curtis, L. A. Stevenson, and Foster J. Curtis.

Special Meeting—A special meeting of the Salt Lake County Medical Society was held at the Commercial Club Thursday, June 11, 1925. Thirty-nine members and two visitors were present.

President John Z. Brown introduced the speaker of the meeting, Dr. James F. Percy of Los Angeles, California.

Dr. Percy talked on "Heat in Cancer." He discussed the history of the cautery. He described his technic in cancer operations using his cautery. He cited many cases from his own experience, showing the advantage of cauterization over the usual method of dealing with malignancy.

His very interesting and instructive paper was discussed by Byron Reese, F. S. Bascom, A. Lipkis, A. A. Kerr, Clark Young, and A. C. Callister.

May 11—Sixty one members and fourteen visitors were present at this meeting.

The scientific program was presented by members of the County Hospital staff, F. E. Straup presiding.

Ray T. Woolsey demonstrated some x-ray films of multiple pregnancy. Edwin R. Murphy presented a case of spasmophilia with laryngospasm and discussed the differential diagnosis and treatment. B. E. Bonar discussed a fatal case of diaphragmatic hernia in the new-born and showed pictures of the pathological specimen. He also showed films of enlarged thymus glands and outlined the clinical history of such a case treated by x-ray. Ralph Tandowsky showed a case of erysipelas and read an instructive paper based on a study of one hundred cases of this disease. George F. Roberts presented a case which had recovered from epidemic spinal meningitis. He discussed the treatment used in the recent epidemic. His case was discussed by G. H. Pace, R. T. Jellison, F. E. Straup, Frank Boucher, and G. E. McBride. Newton Miller presented two cases of scalp wounds and discussed the treatment. C. W. Woodruff presented an undiagnosed case of enlarged spleen. A patient 80 years old, who had been operated on for strangulated hernia, was presented by W. E. Maddison, and the surgical treatment of this condition was outlined by J. C. Landenberger. A case of stone formation in the bladder, due to foreign body, was presented by E. S. Pomeroy, and also a case of perineal fistula cured by dilatation of the urethral stricture.

Guy Van Scoyac showed a case of miners' consumption and a case of advanced pulmonary tuberculosis which had responded to calcium treatment.

These cases were discussed by H. S. Scott, George E. Robison, John Z. Brown, J. C. Landenberger, F. E. Straup, and George W. Middleton.

Fred Stauffer reported for the building committee, and outlined a plan for financing the ten-story building.

May 25—Fifty-six members and three visitors were present at this meeting.

The secretary read communications from the American Birth Control League, Inc., and the State of Utah Mormon Battalion Monument Commission. No action was taken on either of these communications. He also read a

communication from the American Medical Association referring to the auto emblems, and one from Miss Ruth Olson with reference to a position in a doctor's office.

J. C. Landenberger presented a clinical case. The man was struck by lightning, rendering him unconscious, producing superficial burns over the front of the body. He showed the man's clothing, which was peculiarly ripped and torn by the lightning. General discussion followed.

E. L. Skidmore discussed "The Insulin Treatment of Diabetes." He outlined the management in order to determine the tolerance, the administration of insulin, instructions to patients, symptoms of overdosage, treatment of coma and complications. He presented a clinical case which had been treated with insulin for three years. Ralph Pendleton, Mazel Skolfield, and A. A. Kerr discussed Skidmore's paper.

A. J. Hosmer's paper was on "The Acute Abdomen." He sighted many cases from his own practice, discussed the differential diagnoses, time for operation, and technic. The differential diagnoses of surgical conditions was discussed in detail. This instructive paper was discussed by S. H. Allen and E. L. Skidmore.

The applications of L. C. Potter and W. N. Cain were voted upon and they were elected to membership.

President Brown announced that the Visiting Nursing Association wanted a member of the Salt Lake County Medical Society on their board.

William T. Cannon moved that a committee of three be appointed to investigate the proposition and report at the next meeting. Seconded and carried.

Nevada State Medical Association

W. M. EDWARDS, M. D., Mason.....President
CLAUDE E. PIERSALL, M. D., Reno.....
Secretary-Treasurer and Associate Editor for Nevada

THE 1925 SESSION OF THE N. M. A., ELKO, SEPTEMBER 4 AND 5

The 1925 meeting of the Nevada State Medical Association will be held at the Elko General Hospital, Friday and Saturday, September 4 and 5.

It has been announced to a number on our program that it would be September 11 and 12, but the dates are changed so that our program will not conflict with the Utah State Medical meeting and post-graduate course, which will be held September 7 to 12, inclusive.

Friday, September 4, we will have a luncheon at the General Hospital, and Friday evening at the theater, a movie on pulmonary tuberculosis. Saturday evening we will have a real banquet at La Moile, such as we had there in 1921; Saturday will be devoted not only to papers, but to clinical demonstrations. Sunday, September 6, we will have a fishing trip which the Elko County Society maintains may be the best that can be had anywhere in the United States.

The following is a quotation, in part, of Dr. W. A. Shaw's letter to the secretary, dated April 25, 1925: "We intend to have the finest meeting that has ever been put over in the state of Nevada. We put over a meeting in 1921 that we figured could be equaled, but not excelled; Reno apparently excelled our meeting at Bowers Mansion in numbers only. We, in Elko County, shall put on a meeting in September which will be written in the history of the Nevada association and which will also be remembered enthusiastically by all the medical men who attend."

Our Nevada members are urged to present clinical cases, to write to your secretary for a tentative program, then decide what subject you will present or discuss. All members and visitors who are to present a paper or clinical demonstration are urged to send to the secretary a resume of your subjects as early as possible so that those listed for discussion may be prepared for the same.

The Elko Society will provide space for exhibitors.

No member may present or discuss a paper if his dues are unpaid.

The Washoe County Medical Society (reported by

Henry Albert, secretary)—A meeting was held on June 9, with President Vinton A. Muller in the chair.

Dr. Carl H. Lehner's application for membership was referred to the Board of Censors.

A communication from W. C. Woodward of the A. M. A., relative to urging those in charge of the reduction of federal taxes to consider "The discontinuance of the war tax imposed on physicians under the Harrison Narcotic Law by the Revenue Act of 1918," and also "The right to deduct certain professional expenses in the computation of the physician's income tax, which is equivalent to imposing a tax on the activities out of which such expenses arise, namely: (a) A tax on attendance at meetings of medical societies, and (b) a tax on post-graduate study," was read.

A motion to the effect that the Washoe County Medical Society indorse the spirit of this communication and that the secretary be instructed to write to the President of the United States, the Secretary of the Treasury, and to Nevada's representatives in the United States Senate and the House of Representatives, informing them of the action taken, was passed.

Doctor Ernest H. Falconer of San Francisco addressed the society on "Some of the Causes of the Enlarged Spleen." He discussed more especially the leukemias, Hodgkin's disease, splenic anemia, pernicious anemia, hemolytic jaundice, and polycythemia. The address was illustrated with lantern slides and was discussed by Doctors S. Bath and Albert.

Members in attendance were: Albert, Bath, Brown, Caples, Fuller, Lewis, McLean, Muller, Piersall, Samuels, Servoss, Tees, West, and Doctor Lehnner was present as a guest.

CALIFORNIA BOARD OF MEDICAL EXAMINERS' NOTES

(C. B. Pinkham, M. D., Secretary)

Health Fakers as of Old—Although we fully realize the hopeless stupidity of a lot of our "health educators" and are fully cognizant of the flamboyant propaganda and unutterable rot that is ground out in an endless stream and labeled health information, we nevertheless had hoped that after a half generation of such tremendous activity some progress was being made. We had hoped that our "speedy positive health propaganda" would at least enable us to say that Barnum's well-known dictum was at last obsolete. However, there is hardly a mail delivery but what contains stories that cause us to wonder if we really are elevating mass intelligence.

Just recently, a resident of an attractive little town in California became ill and formed the idea that he had a tumor. Instead of going to one of the educated physicians of his community, or even one of the thousands in a nearby city, he went to see a woman of the neighborhood who, according to a newspaper, "combined the business of vending hot tamales with the prescribing of herbs for the illnesses of her customers." This "doctor," it is reported, "told the patient that she could cure him, that it was not a tumor from which he suffered, but that he had in his stomach an animal that lived in a round ball, that the animal had broken out of the ball and was loose in his stomach, and that for the sum of \$40 she would remove the animal and he would then get well. The patient had but \$35 and he offered the "doctor" that amount, but she refused to treat him until the \$40 was paid in advance, so the patient borrowed the other \$5 and paid the \$40. He then went to the home of the "healer" where, on account of limited room, two patients occupy the same bed, regardless of what diseases they may have. The "healer" gave the patient some liquid medicine to drink and put a mustard plaster over his abdomen. On the second day she told the patient she would remove the animal, but that in his weakened condition it would be too much of a shock to him to see what a terrible animal lived in his stomach, so he was blindfolded. A woman patient in the same room was also in too serious a condition to see the terrible animal come from the other patient so she was blindfolded. An emetic was then given the patient who became very sick and vomited into a pan. After he had recovered slightly, the blindfold was removed and he was allowed to see the

animal that had been removed from his stomach. He says he didn't feel the animal come up his throat, but he saw it in the pan, that it had four legs and was partly black in color, and that, although he doesn't know the name of the animal, he has often seen such animals on the rocks in the ocean (probably a small crab). The sick man felt better after "the animal was removed," but the next day the "healer" told him that the ball that the animal formerly lived in was still "under his liver" and that it would have to be removed before he could hope to be entirely well, that it had been necessary to remove the animal first and it would take an entirely different kind of medicine to remove the ball; this would cost \$20 more. The sick man didn't have the other \$20, so it is presumed that the remnants of the ball still remain "under the liver."

Medicine Before the Bench

Findings and Comments of the Courts on Acts and Omissions of Doctors

(EDITOR'S NOTE—*The law reports contain many interesting decisions, involving the reputations and fortunes of doctors. In this column in each issue a brief summary of one or more decisions and comments of the several courts of last resort upon the cases will appear. The matter will be selected by our general counsel, Hartley F. Peart, who, with Hubert T. Morrow, attorney for Southern California, will contribute from time to time.*)

The Legislature at its last session passed an act which becomes law under the signature of the Governor on April 24, 1925, which empowers judges of the Superior Court to call in experts of all kinds to give testimony in cases requiring expert evidence. The law has been added as Section 1871 of the Code of Civil Procedure. The new section is as follows:

Experts; Appointment of by Court or Judge; Compensation; Manner of Examination as Witnesses. Whenever it shall be made to appear to any court or judge thereof, either before or during the trial of any action or proceeding, civil or criminal, pending before such court, that expert evidence is, or will be required by the court or any party to such action or proceeding, such court or judge may, on motion of any party, or on motion of such court or judge, appoint one or more experts to investigate and testify at the trial of such action or proceeding relative to the matter or matters as to which such expert evidence is, or will be required, and such court or judge may fix the compensation of such expert or experts for such services, if any, as such expert or experts may have rendered, in addition to his or their services as a witness or witnesses, at such amount or amounts as to the court or judge may seem reasonable. In all criminal actions and proceedings such compensation so fixed shall be a charge against the county in which such action or proceeding is pending and shall be paid out of the treasury of such county on order of the court or judge. In all civil actions and proceedings such compensation shall, in the first instance, be apportioned and charged to the several parties in such proportion as the court or judge may determine and may thereafter be taxed and allowed in like manner as other costs. Nothing contained in this section shall be deemed or construed so as to prevent any party to any action or proceeding from producing other expert evidence as to such matter or matters, but where other expert witnesses are called by a party to an action or proceeding they shall be entitled to the ordinary witness fees only and such witness fees shall be taxed and allowed in like manner as other witness fees. Any expert so appointed by the court may be called and examined as a witness by any party to such action or proceeding or by the court itself; but, when called, shall be subject to examination and objection as to his competency and qualifications as an expert witness and as to his bias. Such expert though called and examined by the court, may be cross-examined by the several parties to an action or proceeding in such order as the court may direct. When such witness is

called and examined by the court, the several parties shall have the same right to object to the questions asked and the evidence adduced as though such witness were called and examined by an adverse party.

The court or judge may at any time before the trial or during the trial, limit the number of expert witnesses to be called by any party. (In effect 90 days from and after April 24, 1925.)

CORRESPONDENCE

HOW YOSEMITE VALLEY IMPRESSED ONE PHYSICIAN'S WIFE

By M. B. P., San Diego

[If all our guests enjoyed the trip to Yosemite as did the San Diego member's wife who sends us this communication signed with her initials, we might do well to make the "valley" permanent convention headquarters.—EDITOR.]

Yosemite Park is beautiful. No praise that it has had could overdo the subject. To stand on one of those neat paths and look about at the green meadow or watch the clear, flowing river, and then gaze aloft at the imposing "Dome," or see the high rampart of Sentinel Rocks, fills one with praise for the Creator. Then look down at one's comfortable surroundings, and a calm assurance steals over one that all is well in the world. Mankind may enjoy its beauties and be thankful, as much as in him lies, to know that water is abundant for our needs, beauty is here to rest the weary, surprises are ready to give thrills, trees have grown for shade or shelter, flowers are abundant to lead mankind forward with desire for color, grace and charm.

When riding on the winding drives the visitor notices how inviting they look. There are lights and shadows ahead and tall straight pines looking permanent, and small graceful trees swaying to beckon the traveler. The roads are enticing. The woods are delightful, yes, full of delight. The deep steady-flowing river adds charm to many a vista. The waterfalls which leap into Yosemite Valley are every bit as wonderful as they have been painted. The Vernal Falls seem to get the most praise. The Yosemite Falls make a roar which is louder than visitors expect. When the quantity of water increased, the roar increased, but the eye could not detect much difference. The Cascade Falls are rollicking, jolly, vociferous, and happy looking. The Bridal Veil Falls are well named, for the way the water appears at the top as if coming over a head, but at the base the spray and cascades and rapids where it dashes over rocks among trees makes the beholder think only of how wet it is and full of water because he gets the spray.

The chief benefit of a visit to this marvelous valley might well be found in the effect on a small human being when he looks up the sheer high walls of tremendous height and feels awe creep into his very soul. He must look up to his Creator, marveling in such glorious works.

When riding out of the valley to El Portal the beauty is continuous for many miles, and then following down the shore of the Merced River it is attractive with trees on the banks and many curves and numerous rapids, but finally it grows less interesting.

Perhaps it is as gentle a let-down as one could ask.

A New Idea in Pharmacy Advertising—A firm of Spokane pharmacists have secured national publicity because they have inaugurated a new line of advertising. They call themselves "professional pharmacists" and "prescription specialists," and instead of using their paid space to boost patent medicines, hair dyes, beauty promoters, and such, they employ their space to carry helpful health messages to their patrons. One of their advertisements calls attention to dangers inherent in the indiscriminate use of iodine to prevent goitre; another carries a sane message about insulin and its uses, and still another urges people to have a medical examination periodically and to have it done by their family doctor.

ANOTHER POPE TRAVELOGUE

Simson's Camp, Tanganyika,
Via Nairdi, B. E. A.,
April 30, 1925.

My dear Dr. Musgrave:

We are here in the permanent camp of Simson. It is the last untouched game field of Africa. We are located on a high plateau, five or six thousand feet elevation. The morning and evening are cool, the grass plentiful, and isolated thorn trees shade the place. A score of grass huts shelter us and our native porters. There are about twenty-five of these in camp, and no women. The nearest village is thirty-five miles distant. This is Ikoma, once a Portuguese slave market, now only a collection of huts and a few aborigines.

Since coming to camp we have hunted every day. Great migratory herds of wilderbeasts are swarming over the country, zebra bark their short pertussus cough all night around our huts, hyenas titter and wail and laugh, jackals chatter and lions rumble and grumble in the distance. And because of the great number of wilderbeast, I presume that we see ten thousand a day, the lions are plentiful. All night they make their kills and wander home gorged in the early morning hours. We have seen to date eighty-nine lions. Of this number we have killed twelve. Two of these we killed outright with our bows and arrows, and two more we gave mortal wounds to, and they were dispatched to spare them misery. Eight lions have charged us to date. Four of these we stopped at distances less than five yards. Some of these beasts charged without any more provocation than snapping a camera at them, at distances from thirty-five to sixty-five yards. Either they were fretful females, mostly those who had vicarious interests in cubs, suffered insult by proxy, the usual spinster aunt complex, or they were old lions that had recently been deposed and wounded in a family fight, therefore sour on the world at large. I presume this is a dangerous life, but it all seems rather detached, as though it were a section of a cinema film. When they come on they roar and pound the ground like a running quarter-horse. One came in so close he flung himself in a great somersault right in our midst and fell dead ten feet beyond us as we sidestepped.

Smaller game we have not paid much attention to yet. A Thompson's gazelle, three hyenas, a cheeta, a baboon, and a horny badger for the Los Angeles museum, complete our bag to date.

I've carefully studied the gall-bladder and ducts of all these animals—also Topi, Eland, Zebra and Kongoni—for the Mayo Research Department.

Thus far we are in excellent health and can recommend this sort of life for anyone seeking a complete rest with plenty of exercise.

Very cordially yours,

SAXTON POPE.

Mercurochrome-220 Soluble in Genito-urinary Diseases—Of the 525 cases on which F. H. Redewill and J. E. Potter, San Francisco (Journal A. M. A., June 20, 1925), report twenty-nine patients left before treatment was completed. This leaves 496 patients, of whom only twenty-two were not improved or 4.4 per cent of the series. Of the remaining 474 patients, only twenty-four, or 5 per cent, were cured with mercurochrome alone given intravenously. This shows that only in a very few urologic cases can one depend on mercurochrome alone when given intravenously to effect a cure. Nor can one expect with such a maze of symptoms and pathologic conditions as are manifested in the practice of urology that a drug given only by way of the blood stream can be a "cure-all." In scores of these cases, however, by giving topical applications, deep instillations and irrigations of mercurochrome in conjunction with the intravenous medication, remarkable results have been obtained. In nineteen out of twenty-nine arthritis cases and in half the cases of acute gonorrheal rheumatism, marvelous results were obtained with the first few treatments of mercurochrome intravenously. The development of the diphenylcarbazid test for mercury and the mercurochrome kidney function test has materially decreased the number of cases listed as "not improved."

Simplified Infant Feeding

Analysis of **KLIM**

POWDERED WHOLE MILK

	Dry	Liquid *
BUTTERFAT	28.00%	3.33%
CASEIN	21.28%	2.53%
ALBUMIN	54.6%	.65%
LACTOSE	38.00%	4.53%
ASH	5.76%	.69%
WATER	1.50%	88.27%
CALORIES (per ounce)	149.	18.

* 4 1/2 Ounces to a quart of water

KLIM is completely soluble in water of any temperature

When Used in Infant Feeding

Reliquified KLIM at normal strength has the same analysis and caloric value as natural whole cow's milk and is subject to the same modifications when used in infant feeding

KLIM simplifies infant feeding because:

When reliquified it is the same in composition as natural milk.

It is a safe milk free from pathogenes.

It is easily digested due to the flocculent casein and fine butterfat globules, reducing the possibility of colic, and other nutritional disturbances.

It is easy to prepare correctly. Prepared only as needed, lack of ice is no hindrance or danger.

Natural milk may be subject to many variations in purity, acidity, and butterfat content, but KLIM is invariably the same

Literature and samples sent promptly upon request

Recognizing the importance of scientific control, all contact with the laity is predicated on the policy that KLIM be used in infant feeding only according to a physician's formula.

Castle Uses Bronze for Your Greater Protection

Bronze adds indefinitely to the life of your instrument sterilizer in the surgery. It is a seamless, solderless, rivetless casting, and so is a safeguard against trouble and repair charges, should the sterilizer be forgotten.

Rounded corners facilitate cleaning. The heating coil of the steam model is cast right into the metal of the bottom, leaving the bottom smooth and free of residue-catching pockets. The famous Castle simultaneous cover and tray lift is included—a foot lever operates it.

New Utensil Sterilizer

The new mechanical pump is an advantage to the *utensil* sterilizer in addition to the solid bronze cast bottom, sloped for easy drainage. This pump operates efficiently and smoothly by foot and obviates complicated mechanism.

When Sugar is Taboo

In cases where non-sugar diets are essential, Nutradiet canned fruits may be prescribed.

They are highest quality fruits — well-known S & W quality—packed *without syrup*. Sterile water or the natural fruit juice is used instead.

Hence Nutradiet fruits contain less sugar than the fresh fruit itself—a minimum of carbohydrates.—for a portion of the natural sugar is thrown off in the water, after the fruit is canned.

Write for chemical analyses. Also list of grocers selling Nutradiet fruits.

[Nutradiet salt-free vegetables include a variety of vegetables packed without salt or sugar.]

WELLSWORTH TILLYER LENSES

*Perfect Vision from
Edge to Edge*

In introducing Wellsworth Tillyer Lenses we believe that we are offering you the finest ophthalmic lenses obtainable. Never before, have corrected lenses of such minute precision and perfection been produced in commercial quantities.

What are Tillyer Lenses?

- 1—They are the only lenses which are corrected both for astigmatism and power.
- 2—They give the same clear and distinct vision in the marginal portions as in the center.
- 3—The usual errors of astigmatism and power in the margin of ordinary lenses have been remedied.
- 4—They give perfect vision when the eyes look obliquely through the lenses.
- 5—They are ground to exact effective power or vertex refraction both in center and in margins.
- 6—They have a much finer polish than ordinary lenses, making details visible with unusual clarity.
- 7—They are obtainable in plus powers up to 7 D. and in minus up to 20 D. inclusive.
- 8—They are regularly supplied in white glass, but can also be obtained in Cruxite and colored glasses.
- 9—They are supplied in Wellsworth Monaxial, Ultex and Kryptok Bifocals on prescription, from the factory.
- 10—Every Wellsworth Tillyer lens has the © monogram lightly etched on the margin—your safeguard and guarantee of the genuine.

SAFE MILK FOR INFANT FEEDING

The Original

During the hot summer season care should be exercised in the selection of milk used for infant feeding.

Horlick's Malted Milk is prepared from clean, fresh, full-cream milk, combined with the extracts of malted barley and wheat. Well balanced, partially pre-digested and conveniently prepared.

"Horlick's" is readily adapted to individual infant feeding, strengthens and invigorates delicate children, and is used with benefit as a nourishing food-drink for nursing mothers. Prescribed by the medical profession over one-third of a century.

*Samples and literature prepaid
upon request*

AVOID IMITATIONS

Horlick's Malted Milk Co.
Racine, Wis.

Effects of Radiations of Cod Liver Oil—Ultraviolet light is bactericidal. Gates, for example, showed the lethal action of ultraviolet radiations on staphylococcus aureus. To I. A. Manville, Portland, Oregon (Journal A. M. A.), it seemed reasonable to assume, in view of the foregoing facts, that the reason rats failed to develop infections when raised on diets containing the fat soluble vitamin was the bactericidal action of the ultraviolet radiations that are now known to characterize such fats. In order to prove this hypothesis, bacterial cultures were exposed to cod liver oil. During the exposure, the cod liver oil, rendered alkaline, was oxygenated. The results of these experiments strongly indicate an inhibitory action of cod liver oil on bacterial growth. Besides the action of cod liver oil in curing or preventing rickets, Manville concludes that there are two other specific actions: (a) There is a stimulation of cell activity and a distinct inhibitory effect on bacterial growth; (b) when these active substances are in excess of the amount producing stimulation, there is exerted a depressing action, the most striking manifestation of which is a lack of fertility. The separation of fat soluble A into two separate vitamins each with a specific action does not seem justified when the effects can be explained as being due to different concentrations of the same principle.

Acute Toxic Encephalitis of Nasal Sinus Origin—One of the patients whose case is reviewed by E. T. Gatewood, Richmond, Virginia (Journal A. M. A.), was evidently suffering from a mild progressive toxic encephalitis secondary to the suppurative ethmoiditis, probably by direct continuity. The second case suggests a violent toxic absorption. Gatewood says that cases simulating this picture frequently lead to brain operations with disastrous results. Patients manifesting such symptoms should emphasize the importance of a careful rhinologic examination. As the symptoms are toxic in nature, the improvement may be sudden or gradual after the eradication of the septic focus.

If its for the physician, hospital or sickroom, we have it

Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in—

ALQUA
THE IMPROVED
ALKALINE WATER

ALQUA WATER contains the alkaline salts found normally in the human body. Physicians will find it invaluable where alkaline treatment is indicated. Not only is it very effective in the treatment of most acute and chronic diseases caused or accompanied by acidosis, but it is an ideal preventive, in that it neutralizes destructive acid by-products in the system.

GLACIER SPRING WATER with which Alqua is prepared, originates in the upper glaciers of Mt. Shasta, California, U. S. A., (Elevation 14,442 ft.) Its great purity without artificial treatment, renders it especially suitable for affinitization with the added salts, thus forming a combination that is remarkable as an alkaline water. Glacier water is released from the earth at Shaste Springs where it is put into block-tin lined carriers and transported to the Company's laboratory where the alkaline salts are scientifically added under the directions of an expert chemist, thereby creating, through the united efforts of science and nature, the wonderful medicinal virtues of Alqua Water. ASK YOUR PHYSICIAN ABOUT IT.

At All Druggists

The Management of an Infant's Diet

Summer Diarrhea

Mellin's Food
Water (boiled, then cooled)

4 level tablespoonfuls
16 fluidounces

This formula provides a means of supplying the principal fuel utilized in the body for the production of heat and energy and furnishes immediately available nutrition well suited to protect the proteins of the body, to prevent rapid loss of weight, to resist the activity of putrefactive bacteria, and to favor a retention of fluids and salts in the body tissues.

While the condition of the baby will guide the physician in regard to the amount and intervals of feeding, the usual custom is to give one to three ounces every hour or two until the stools lessen in number and improve in character. The food mixture may then be gradually strengthened by substituting one ounce of skimmed milk for one ounce of water until the amount of skimmed milk is equal to the quantity of milk usually employed in normal conditions.

Mellin's Food Co., 177 State Street Boston, Mass.

FRENCH HOSPITAL

French Mutual Benevolent Society, founded in 1851

Geary Street at Fifth Avenue

San Francisco, Calif.

General hospital of 220 beds, accepting all cases except mental diseases. Built upon the pavilion plan, allowing large air space for each patient. PHONE METROPOLITAN 5044 LOS ANGELES

The Romance of Medicine—William D. Haggard, Nashville, Tenn. (Journal A. M. A.), reviews the progress made in medicine in the last fifty years. He says that medicine is the only profession that is literally and altruistically devoted to professional suicide. It endeavors chiefly, not alone to cure, but to prevent disease, and thus to banish from mankind pain, suffering, and ultimate death from maladies of the flesh. But what it cannot prevent it must cure. What it cannot cure it must palliate. The discovery of the germ of tuberculosis, "the Captain of the men of Death," was the beginning of the annihilation of the Great White Plague and is a more important victory for mankind than resulted from the Fifteen Decisive Battles of the World. That the spirochete was the actual cause of syphilis, the great Black Plague, was discovered by Schaudinn in 1905. A romance in medicine to grip the admiration of the world is the subjugation of typhoid fever. Most dramatic among modern victories is the conquest of yellow fever. In the last decade, many diseases of the heart, kidneys, gall-bladder and other organs have been shown to be derived frequently from the foci of infection around the teeth, in the tonsils, in the sinuses of the nose, and in other structures. This great discovery has enabled the physician to administer in many cases the most effective of all treatments, the removal of the cause. The discovery of radium by Madam Curie close on the discovery of the roentgen ray by Roentgen in 1896 was not only a triumph in wresting another secret from the physical world, but has furnished a most necromantic weapon for the cure of certain forms of cancer and for its palliation in hopelessly neglected cases. The use of safe drugs for local injection in rendering surgical operations painless is now like a performance in a world of magic. Anti-tetanic serum to prevent lockjaw is the king of preventive serums. Physicians and the whole world are daily debtors to the innumerable instruments of precision, to the blood pressure apparatus, the basal metabolism rate machines, and the newer instruments for administering gases, that render anesthesia almost totally devoid of danger. What is more astounding than the revelation in the last few decades of the part

played in our bodies and lives by the wonder-working ductless glands? The greatest romance of the last few years in medicine was the discovery of insulin by Banting. The solution of the pellagra problem seems nearer with the increasing belief that pellagra is a deficiency disease, possibly from a shortage of vitamins, and seems to be caused by faulty protein food mixture and is generally benefited by fresh meat and milk. The most threatening cloud of chronic disease in the South, hookworm, has been dissolved by the wand of Aesculapius. The real romance of present-day medicine is to prevent or to discover early the degenerative conditions of the great organs—the heart, kidneys, liver, and brain. All the saving in life has been in the prevention of infant mortality in the control of contagious diseases. Eternal vigilance of every individual by his physician is the price of lengthened life in the middle-aged. Community health is much in advance of the prevention of illness in the individual. *Have a thorough physical examination on your birthday!* It should be a real survey of a man's physical as well as mental status. It is estimated that the number of cases of sickness in this country in a year is thirteen and a half million, costing the nation a billion dollars. It is astounding to think that there are 225,000,000 days of sickness a year in the United States. If it were possible, by nationwide effort, to reduce the amount of sickness by 25 per cent, the total economic gain yearly would be around a quarter of a billion dollars. The people should be taught that in truth there can no more be different "schools" of medicine than there can be different schools of physics, or of mathematics or astronomy. There is nothing under the sun which is of proved value that has not and will not be used by the profession in the treatment of disease. All non-medical agencies are enthusiastic endorsers of health examinations. A health week should be established nationally by all the health agencies of this country, with the co-operation of every one of the 90,000 members of the American Medical Association. The press can be counted on to do its part, which is an essential, as it is unfalteringly interested and helpful in all health movements.

St. Joseph's Hospital

Buena Vista and Park Hill Aves., San Francisco

Accredited by the American Medical Association, American College of Surgeons. Accredited School of Nursing. Open to all Members of the California Medical Association.

A limited general hospital of 200 beds, owned and operated by the Franciscan Sisters of the Sacred Heart. All classes of patients admitted except those suffering from communicable and mental diseases. This hospital was organized in 1889 and has been in continuous operation since that date. A modern annex was built in 1906. A further extensive building program is now under way.

SITUATIONS WANTED—Salaried Appointments for Class A physicians in all branches of the Medical Profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan, Chicago. Established 1896. Member The Chicago Association of Commerce.

MEDICAL JOURNALS—WE WISH TO PURCHASE MEDICAL JOURNALS, complete files, volumes and copies. Domestic and foreign, bound or unbound. Have for sale complete files and odd volumes of Medical and Chemical Research magazines. Please send us lists of your wants. B. Login & Son, 29 East 21st Street, New York.

INDUSTRIAL POSITION WANTED; MINING OR LUMBER PREFERRED. Preference location California, Nevada or Arizona. Class A graduate Northwestern; 12 years' practice; industrial work exclusively for the past three years. Age 38, married; wife can take charge of small hospital if desired. Available July 1. Address Box No. 715, CALIFORNIA AND WESTERN MEDICINE.

EXCELLENT OPPORTUNITY FOR EYE, EAR, NOSE, THROAT MAN, and a Dentist, to associate with established physicians for group work. Must be high grade men. Address CLINIC, care of CALIFORNIA AND WESTERN MEDICINE.

INDUSTRIAL POSITION WANTED—MINING OR LUMBER PREFERRED; preference of location Arizona, Nevada or California. Class A Physician and Surgeon (Graduate Northwestern); 12 years' practice; industrial accident work exclusively for past three years; age 38; married; wife can take charge of small hospital if desired. Available on June 15. Address Dr. 700, CALIFORNIA AND WESTERN MEDICINE.

An Interesting Medico-Legal Decision—The Lord Chief Justice, summing up in a case in which a doctor was accused of negligence, pointed out that a barrister, a poet, a statesman, or a dignitary of the church, who, by negligent conduct, imperiled the fortune of a case, the taste of the public, the interests of the nation, or the future of an immortal soul was not liable for damages. What retribution eventually awaited him did not involve him in any such liability. Doctors, however, like chauffeurs, engine-drivers and solicitors, were in another group, and were bound at their peril to use reasonable care. The jury returned a verdict for the doctor. Judgment was entered accordingly.—London Times.

SITUATIONS WANTED

WANTED—Part or whole time, permanent or locum tenens appointments for class A physicians; candidates located in every section of the country; personal interviews conveniently obtainable; no charge to employers for the introduction of candidates. Medical Bureau, Marshall Field Annex, Chicago.

WANTED—Tuberculosis appointment by class A physician; special study at Saranac Lake; two years' institutional experience; several years' specialized practice (diseases of the chest, including pneumothorax and x-ray). Medical Bureau, Marshall Field Annex, Chicago.

WANTED—Surgical appointment; preferably with a group clinic; M. D., Johns Hopkins; has had splendid hospital connections; considerable special work in surgery; a number of years of private surgical practice. Medical Bureau, Marshall Field Annex, Chicago.

WANTED—Assistantship or institutional appointment; M. D., University of Pennsylvania; a two-year rotating internship; nine months' special work in surgery; qualified in pathology; excellent personal qualifications; age 28. Medical Bureau, Marshall Field Annex, Chicago.

Facial Palsy Following Scarlet Fever—Two cases of unilateral peripheral facial palsy are reported by P. N. Mutschmann, Calumet, Iowa (Journal A. M. A.). Both cases followed attacks of scarlet fever, with apparently only a moderate degree of glandular involvement, and both, after several months of apparently complete clinical recovery, have developed an intermittent paralysis of the seventh nerve on the right side.

ACIDOSIS

By some investigators ACIDOSIS has been designated as a diminution of the alkalinity in the blood; by some as an excess of acid in the blood; by others as a lessening of reserve supply of fixed bases in the blood.

If the acid combining power of the blood is impaired BY A LACK of the alkalies, sodium bicarbonate and sodium phosphate, and may be built up by the process of food ingestion, *may we ask* attention to CALSO WATER, which is rich in the potential alkalies.

CALCREOSE

R. RAMSDEN WADE reports (Brit. M. J. 1: 158, Jan. 24, 1925) having had good results from the administration of creosote in the treatment of cases of influenzal pneumonia and chronic influenza which are very liable to be mistaken for phthisis.

POWDER—TABLETS
SOLUTION

CALCREOSE (calcium creosote) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime. It has the pharmacologic activity of creosote, but apparently does not have any untoward effect on the stomach.

ALUM ROCK SANATORIUM

FOR THE TREATMENT OF TUBERCULOSIS IN ALL ITS FORMS

The Sanatorium adjoins Alum Rock in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

Hunting With the Bow & Arrow

BY DR. SAXTON POPE

An attractive volume containing 256 pages and 50 illustrations, printed on art paper, substantially bound in buckram with stiff board covers and crash russet sides appropriate to outdoors. There are sixteen chapters, each dealing with some phase of archery. They describe the Indian methods of using the bow; how to make bows and arrows; the ballistics of archery; how to shoot; hunting small game — the coon, fox, coyote — and relate experiences in killing deer, mountain lion and bear with bow and arrow. The illustrations are from photographs taken in the field and give the reader a clear picture of the hunting scenes. It is a book that every archer and sportsman should have in his library and should be read by all who love this fair sport and adventure.

A part of the "American" installation in the Mater Misericordiae Hospital laundry.

The New Mater Misericordiae Hospital at Sacramento, California. This hospital is in charge of Sisters of Mercy.

And at Sacramento's New Hospital

The new Mater Misericordiae Hospital, at Sacramento, California, will handle its own laundry work with an installation of "American" laundry machinery. For those responsible for managing this institution, know that the hospital-operated laundry means closer supervision of the work and greater economy. A smaller supply of linens may be maintained, for instance, because of the speed with which they can be laundered and returned to service. Like the directors of other representative

hospitals throughout the country desiring efficiency and dependability, they selected "American" machinery for the laundry equipment.

Your hospital, too, will profit from the establishment of a hospital laundry, equipped with "American" laundry machines. We maintain a corps of laundry experts who will be glad to consult with you concerning any problems of laundry installation or management. Simply write.

BOOK REVIEWS

This column is conducted solely in the interests of California and Western Medicine readers. Critical comment, favorable and unfavorable, purely from the standpoint of the interests of the medical reader, will be made about books selected from the larger number acknowledged in the Books Received column. The advertising columns are open to book publishers who wish to make additional statements about their publications.

The Treatment of Common Disorders of Digestion. By John L. Kantor. 245 pages. Illustrated. St. Louis: C. V. Mosby Company. 1924. Price, \$4.75.

This little volume of 245 pages should prove of value to the general practitioner and student, as it treats in a simple, direct manner some of the common disorders of digestion, giving "principles and objectives of therapy," describing and outlining suitable diets. It is profusely illustrated.

However, it would seem that the author stopped too soon in his work and that he would have rendered a greater service if he had more thoroughly covered the field of gastro-intestinal disorders. W. W. B.

Anesthesia for Nurses. By Colonel William Webster. 153 pages. Illustrated. St. Louis: C. V. Mosby Company. 1924.

Colonel William Webster, who recently published *The Science and Art of Anesthesia*, reviewed in these columns, for the use of physicians and surgeons, presents a condensation of this work in his *Anesthesia for Nurses*.

In the preface, the purpose of the book is shown to be an aid to the nurses in the sparsely settled districts of the Western States and the Canadian West and to those working as missionaries in China and India, who are called upon to administer anesthetics because of the dearth of physicians in those places.

To any nurse ambitious to take up anesthetics as a profession, with the object of practicing in the hospitals of centers where men and women qualified in medicine are available, he recommends a medical course at some good university in order to obtain the minimum necessary knowledge required by an anesthetist, i. e.:

1. "To be able to make adequate preliminary examina-

tion, or to properly interpret and correlate the findings of others and direct the patient's preparation.

2. "To choose the most suitable anesthetic and produce a smooth and pleasant induction.

3. "To maintain the patient on the least amount of anesthetic consistent with the surgical procedure.

4. "To instantly recognize and be prepared to remedy with quiet confidence any untoward symptom which may arise."

The book is eminently suited to the purpose for which it is written and the chapter on pre-operative and post-operative care of the patient makes it a valuable addition to the teaching of nurses.

San Francisco

Hemlock 2220

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of

them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) \$45.00 per week and upward.

ARLCO—POLLENS

were originated to make possible the scientific study of hay fever.

They made available for the first time a proper assortment of individualized diagnostic and treatment pollens—permitting thereby differential diagnoses, specific treatment and the development of an authentic literature on

HAY FEVER

The number and diversity of pollens have been constantly increased until they now cover the more essential requirements of the entire country.

But the constant seeking and studying of new pollens will continue in order to permit in future even finer distinctions of diagnosis and to assure still more accurate treatment.

R for--when summer comes

Thousands of mothers are thankful to their physicians for prescribing Dennos—especially during the trying summer months.

The method of preparation requires cooking. The starch in Dennos acts as a protective colloid. Dennos babies seldom develop fermentative diarrhea.

The cereal of Dennos is largely whole wheat, which aids in the retention of the calcium and magnesium salts and often produces a better gain in weight.

Samples and literature sent on request

This Sign Is Your Protection

It assures you that the dealer who displays it is reliable and that he distributes a product of unquestioned merit.

By the way, has it ever occurred to you that your outlay for equipment is the sum of two components, a relatively **LARGE** amount representing the minimum cost from any source, plus a relatively **SMALL** amount representing refinements in quality, convenience, and service? Have you also reflected that what the smaller amount purchases is vastly more important to you than what the larger amount covers?

You are therefore thwarting your own interests if you are swayed by price alone, especially when a very slight additional outlay will equip your office with

ALBATROSS METAL FURNITURE

the product of a responsible firm, absolutely guaranteed without limit as to time against defects in materials or workmanship, and sold by the most reliable and enterprising dealers everywhere.

Remember, the annoyance and inconvenience attendant upon using equipment poorly constructed and incorrectly designed persist and grow from day to day. Remember, too, that in their stead at a very moderate increase in the initial cost you may have the pleasure derived from the convenience and attractiveness of **ALBATROSS FURNITURE** and this, too, will be enhanced rather than diminished with the lapse of time.

This Sign Is Also Your Protection

It appears on every piece of Albatross equipment, identifies it as an Albatross product and therefore insures its satisfactory performance.

i. Title.

Dict. 3. Menus.

RC814.J7

1. Mix one fluid drachm of Squibb's Liquid Petrolatum with Agar with five fluid drachms of water.

2. Pour the mixture into a test tube and heat to boiling point over a Bunsen burner or alcohol flame. Then cool under running water until thoroughly cold.

3. The material in test tube will be found to be a jelly, no longer fluid, and will not pour even though tube is turned up-side-down. Any other product of this character on the market can also be easily tested for agar content by the same method. If the agar content is low, the material in the test tube will not solidify, but will remain in its original liquid form.

Test for Yourself the Superiority of SQUIBB'S LIQUID PETROLATUM WITH AGAR

SQUIBB'S LIQUID PETROLATUM WITH AGAR contains about 30% of agar gel, or "prepared" agar, equivalent to $1\frac{1}{2}\%$ of dry agar. Proof of this exceptional agar content can easily be substantiated through a simple test that clearly indicates the superiority of this new Squibb Product.

SQUIBB'S LIQUID PETROLATUM WITH AGAR was developed by the Squibb Laboratories in response to a growing demand of the Medical Profession for a product that could be prescribed with confidence. It is especially intended for patients who have an aversion for plain oils; or for those who need the combined therapeutic effects of a lubricating mineral oil and the bulk supplied by agar.

This smooth creamy emulsion is readily taken by the most fastidious because of its pleasant taste. It does not separate on standing.

This product contains no phenolphthalein.

Combining an active cathartic with a physiologically indifferent intestinal lubricant, is unscientific and irrational—especially when the product is intended for continued use.

INFANT DIET

MATERIALS

Choosing an Infant's Diet

If all babies were *alike* and *standardized*, then one food would probably take care of the nutritional requirements of most babies.

BUT—physicians know that foods must be altered to suit the nutritional requirements of each infant.

MEAD'S INFANT DIET MATERIALS are helping physicians to do *scientific* infant feeding.

MEAD'S DEXTRI-MALTOSE (the carbohydrate of choice for modified cow's milk mixtures).

MEAD'S CASEC (a useful adjunct when the baby is suffering from Fermentative Diarrhea).

MEAD'S STANDARDIZED COD LIVER OIL (as important to protect the infant from Rickets as orange juice protects from scurvy).

The Mead Policy

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

Authors are responsible for all statements, conclusions and methods of presenting their subjects. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the method of presenting their subjects. It is believed that the author's presentation determines to no small degree the value of his conclusions.

Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented as little disturbed as possible by the editors.

However, the right to reduce or reject any article is always reserved.

Superior Products

Neo-Arsphenamine
DERMATOLOGICAL RESEARCH LAB

GUARANTEE

EVERY batch of Neoarsphenamine, D. R. L., now made is guaranteed to have met a test for toleration almost 75% above governmental requirements.

Here is uniformity as remarkable as it is unprecedented.

In therapeutic results this unusual product compares favorably with Arsphenamine.

Sulpharsphenamine

THE Dermatological Research Laboratories were the first in America to manufacture Sulpharsphenamine, as well as Arsphenamine and Neoarsphenamine. This product is of a quality that justly entitles it to be listed with the D.R.L. line of superior anti-syphilitic drugs.

Potassium Bismuth Tartrate
With Butyn

PURITY of compound, high bismuth content and better absorption and elimination, coupled with practically complete freedom from pain characterize the D.R.L. product.

Preferable to mercury in most cases with greater spirocheticidal power and lower toxicity.

Insist upon D.R.L. products from your dealer.

Monograph on "The Treatment of Syphilis" sent on request.

MERCURETTES

CLEANLY ~ EFFECTIVE ~ CONVENIENT

MERCURETTES will appeal to your patients. They are made of cacao butter in oblong blocks delicately and pleasantly perfumed and their use is not betrayed by the odor and messiness suggesting blue ointment.

Each block or briquette contains 50 grains of metallic mercury very finely subdivided and thoroughly distributed throughout the cacao butter base. It is wrapped in wax tissue and tinfoil.

Any required dose for a mercurial rub can be easily and accurately obtained without soiling the fingers, by cutting the block through the wrappers into the desired number of parts.

Mercurettes are supplied in boxes of 6 blocks and in bulk in packages of 50 and 100 blocks. Your druggist has Mercurettes in stock.

*Literature on Mercurettes will be gladly sent to
physicians on request.*

“The Cathartic Whip”

DESHELL STARCHLESS AGAR FLAKES

So much interest has been created in the superior American made agar used in PETROL-AGAR that we have decided to place it on the market as DESHELL STARCHLESS AGAR FLAKES, for the physician who may wish to prescribe agar.

DESHELL STARCHLESS AGAR FLAKES are produced in a modern American factory on the California coast.

They are free from impurities, sterilized, free from starch—which affords at least 25 per cent additional bulk.

DESHELL STARCHLESS AGAR FLAKES are unusually palatable.

They can be obtained on prescription from any pharmacy.

WHIP a horse continually, and it reaches the stage where it will not move without the whip.

Whip the bowel with a cathartic, and soon it will reach the stage where it will be unable to move without the application of the “Cathartic Whip.”

Chemical injury to the mucous membrane of the bowel can be caused by using cathartics over a long period. These produce a chronic inflammation, which of necessity requires increased amounts to obtain response.

The bowel moves from a “cathartic whip” because it is hurt.

There is a way to teach the bowel to move normally without hurting it. This is by the creation of a normal “Habit Time,” which can be accomplished by diet, exercise, and the use of a mechanical aid to re-educate the bowel.

PETROLAGAR is issued as the mechanical aid in such a condition.

It is an emulsification of pure mineral oil with agar-agar. The agar serves to distribute the mineral oil thoroughly through the feces, providing a soft, easily moved mass.

The agar now being used in **PETROL-AGAR** is an American-made agar—a superior product, free from starch, which affords at least 25% additional bulk.

PETROLAGAR has been accepted for New and Non-official Remedies by the Council on Pharmacy and Chemistry of the American Medical Association.

PETROLAGAR is issued as follows: **PETROLAGAR** (Plain); **PETROLAGAR** (with Phenolphthalein); **PETROLAGAR** (Alkaline), and **PETROLAGAR** (Unsweetened, no sugar).

TRUTH ABOUT MEDICINES

New and Non-official Remedies

(Abstracts from reports of Council on Pharmacy and Chemistry, A. M. A.)

Note—These do not represent all of the actions of the Council, but they do represent those remedies manufactured by firms who co-operate with California and Western Medicine in its advertising columns, and thereby with the physicians in California.

In addition to the articles enumerated in our last report, the following have been accepted:

Parke, Davis & Co.—Tuna Fish Protein Diagnostic.—P. D. & Co.

Typhoid Vaccine—P. D. & Co., (New and Non-official Remedies, 1925, p. 363). This is also marketed in packages of thirty ampules, ten containing 500 million and twenty containing 1000 million killed typhoid bacilli each. Parke, Davis & Co., Detroit.

Typhoid Paratyphoid Vaccine—P. D. & Co. (New and Non-official Remedies, 1925, p. 363). This is also marketed in packages of thirty ampules, ten containing 500 million killed typhoid bacilli, 375 million killed paratyphoid A and 375 million killed paratyphoid B bacilli, and twenty containing 1000 million killed typhoid bacilli, 750 million killed paratyphoid A and 750 million killed paratyphoid B bacilli. Parke, Davis & Co., Detroit. (Jour. A. M. A.)

Stovarsol — Acetylaminohydroxyphenylarsonic Acid —Stovarsol contains from 27.1 to 27.4 per cent of arsenic. Stovarsol has been reported to produce favorable effects in the treatment of amebic dysentery. It is claimed to yield satisfactory results, both in the eradication of dysenteriae cysts and encysted flagellates and for general amebic dysentery. Stovarsol is not proposed for the treatment of syphilis and its use in amebic infections is still in the experimental stage. Stovarsol is supplied in tablets containing 0.25 gm. Powers-Weightman-Rosengarten Co., Philadelphia.

Sweltering Noon-days and Chilly Evenings

QUICK temperature changes—overconfidence in the ability of the human body to adapt itself to sudden changes—that in brief is the story of the coughs and colds of late August.

Here is another condition in which Thiocol Syrup “Roche” will serve you well. For in Thiocol you have a sedative expectorant that exerts a beneficial effect on the respiratory tract and definitely aids in subduing the cough. This syrup isn’t too sweet, like so many cough syrups, and does not upset the digestion; nor does it constipate. It is a simple remedy, containing only one drug—Thiocol—and is free from any narcotic or palliative constituents. It is never advertised direct to the laity and is intended for prescription only.

Try Thiocol Syrup “Roche” in your next cases of coughs and colds and observe the results.

Literature and Supplies for trial on request

The Hoffmann-La Roche Chemical Works, New York
Makers of Medicines of Rare Quality

The Selection of a Sanatorium

Attention of physicians is called to the urgent need and demand for an up-to-date institution for the scientific care and treatment of psychopaths, functional or organic nervous patients who are not subject to state hospital commitment, and for whom there are inadequate private places except those of a mere boarding-house character devoid of scientific directorship or resident physician and more concerned with financial returns than the recovery of patients.

Our state hospitals are intended to meet this demand, but owing to limited funds are unable to furnish that degree of privacy, home comforts, select environment, close personal touch and careful individualization demanded by patients who are accustomed to and can afford to pay for same—patients to whom money is no object provided they can be restored to health.

Unselfishly, in the interest of medical science to mutual advantage of physician and patient, the Grande Vista Sanatorium proposes an extensive program of reorganization and expansion, placing its directorship into the hands of a medical board who will be authorized to issue shares of stock in the institution to physicians who are in sympathy with this project, and who will lend their good-will and moral support towards its upbuilding.

All physicians of good repute are requested to join in the furtherance of this project, which will prove to their interest, as well as a blessing to their patients.

E. BILHUBER, Inc. 25 West Broadway
New York, N. Y.

Fungicidal Activity of Certain Volatile Oils and Stearoptens—H. B. Myers and C. H. Thienes, Portland, Ore. (Journal A. M. A., June 27, 1925), describe an occupational dermatosis which is seen developing among employes engaged in preparing the fruit for canning. The lesion has been referred to by those affected as a "fruit poisoning." It has been treated without much success by a great variety of means, chiefly by the antiseptics commonly utilized in treating bacterial infections. Scrapings from the lesion revealed budding spore forms with mycelium attached. A 10 per cent alcoholic solution of the oil of cinnamon was painted over the inflamed area. Rapid improvement in the appearance of the lesion, progressing to healing, followed the application of the cinnamon solution. The favorable action of oil of cinnamon on the original and experimental lesions led to an investigation of the comparative toxicities of several volatile oils and stearoptens on cultures of the pathogenic yeast responsible for the infections. Thymol, oil of cinnamon and oil of clove have been found particularly efficacious in destroying the pathogenic yeastlike organism responsible for this dermatitis. The drugs mentioned have been found equally valuable in causing an immediate improvement, progressing to healing of infections apparently due to fungoid organisms of several types.

Not Theory But Practice—That the American Laundry Machinery Company believes the following, which was published in their excellent house organ, The Outlook, is attested monthly in these pages:

"One step won't take you very far;
You've got to keep on walking.
One word won't tell folks who you are;
You've got to keep on talking.
One inch won't make you very tall;
You've got to keep on growing.
One little ad won't do it all;
You've got to keep them going."

It Is a Family Duty to Carry a Medical Protective Contract

The necessity is emphasized by the facts in file No. 03596. The following was received from our local attorneys, while the case was in process of litigation.

"I beg to advise that today Mrs. ———, the wife of your assured in this case, called me by phone and advised that her husband, Dr. ———, had died on March 24.

"The case is now pending on demurrer and it is not likely that much if anything will ever be done with it, although of course they can go ahead and have the administrator or executor substituted."

After a lapse of six months the widow was served with a summons and in advising us, said among other things:

"The Medical Protective Co.,
Fort Wayne, Ind.
Gentlemen:

* * *

I suppose they think that my husband, Dr. ———, left a lot of money. The whole thing does not amount to Five Thousand Dollars, and I have three small children to raise."

The Doctor dead and the defense handicapped because he is not present to prove the propriety of his treatment, the widow financially unable to pay for own defense and endure a judgment; the raising and educating of three children dependent upon the wisdom of the Doctor in carrying a Medical Protective Contract.

*Twenty Per Cent of Wisdom Consists of
Being Wise in Time*

Reduction of Increased Intracranial Pressure—Max M. Peet, Ann Arbor, Mich. (Journal A. M. A., June 27, 1925), says that the slow reduction of increased intracranial pressure in the absence of shock, hemorrhage, vomiting or dehydration is satisfactorily accomplished by the oral or rectal administration of magnesium sulphate. The rapid reduction of intracranial tension, in acute intracranial traumas unassociated with shock, is best accomplished by the intravenous administration of hypertonic Ringer's solution. Glucose may be given later to maintain the lowered intracranial pressure. Hypertonic glucose solution, administered intravenously, is indicated when acute intracranial pressure is associated with shock or hemorrhage, and in the less acute cases when complicated by dehydration, nausea and vomiting. Glucose has the following advantages over any of the salt solutions: prolonged action, no terminal rise in pressure, nontoxicity, nondehydration, increased blood volume in shock, and the control of acidosis.

Extra-Abdominal Conditions Simulating Acute Abdominal Diseases—David Riesman, Philadelphia (Journal A. M. A., June 27, 1925), discusses those extra-abdominal diseases which may simulate acute abdominal conditions, pneumonia, pleurisy, pericarditis, coronary thrombosis, rupture of a dissecting aneurysm of the aorta, true angina pectoris, tabes dorsalis, uremia, tonsillitis, lead poisoning, hysteria, diabetes, thyrotoxicosis, angiospasm of the abdominal arteries, the so-called erythema group of diseases and herpes zoster, not only for the purpose of discussing the intra-abdominal causes of acute abdominal symptoms, but to point out those extra-abdominal conditions which, in their close mimicry of truly abdominal diseases, create diagnostic difficulties and lead to errors in judgment resulting in unwise and dangerous procedures.

MARY'S HELP HOSPITAL

145 Guerrero Street, San Francisco

Accredited for Intern Training by the American Medical Association.

Accredited School of Nursing.

Open to All Members of the California Medical Association.

Institutional Member League for the Conservation of Public Health.

A limited general hospital of 150 beds, owned by the Archdiocese of San Francisco, and operated by the Sisters of Charity. All classes of patients are admitted except those suffering from communicable or mental diseases. The hospital was organized and incorporated in 1892. All buildings were destroyed by the fire in 1906. A complete new modern hospital was finished July 2, 1912. Mary's Help Hospital is well located, well constructed, well arranged, and well equipped for good service.

Are You a Specialist?

Of course you are! You may be a "family doctor" of the good old variety—but nevertheless you are a specialist. You specialize in curing the physical [and sometimes mental] ills of humanity.

But the chances are you do not also specialize in business—investment securities—property values—collections and disbursements—the host of routine business details forced upon the attention of the professional man.

May we relieve you of the burden of those details? We are specialists. We can care for them at a lesser cost than you can yourself.

The Selection of a Physician

The selection of a physician for an operation or as a family doctor, is usually made with some care. We consult those who have employed physicians and are governed largely by their recommendations. But having selected a physician, we follow his advice. We trust him even to the extent of submitting to operations that may have serious results.

THE POINT IS, WE TRUST THE MAN
WHO KNOWS

Now, doctor, the institutions and the firms advertised in this Journal were carefully investigated before their announcements were printed here. The medicinal products were submitted to laboratory tests before they were accepted by the Council on Pharmacy and Chemistry.

On this same principle, that patients trust you about matters with which you are informed, so your publishers urge you to trust their judgment and *buy goods from the advertisers who are admitted to these pages.* Other considerations being equal, you should give your advertisers PREFERENCE because you know they are believed to be trustworthy. Don't speculate or experiment! Trust the APPROVED firms and goods.

The Hartung Hospital Silent Call Signal System

SAFE ————— SILENT ————— SIMPLE

Fully Guaranteed - - Troubleproof

The calling station herewith illustrated shows one of the sixteen combinations that we have to offer.

This station consists of the control switch with ball chain, slip connector, pull cord and pear shaped pendant attached. A slight pull on the cord illuminates a lamp in back of the ruby bull's eye located in the calling station visible to the patient, a lamp over the door in the corridor, a red pilot lamp in diet kitchen and utility room, and the lamp in the annunciator which shows the number of the room calling. These lamps continue to burn until the call is answered and the control switch knob is restored to off position by the nurse.

The push and pull emergency switch is used by the nurse only when she finds the patient in a critical condition and needs immediate assistance. The nurse, pulling out the button of the emergency switch, illuminates a green lamp in the corridor over the door of the room, a green pilot light in the superintendent's office, at the nurses' station, and wherever desired. This emergency call is restored, when answered, by pressing the button of the switch, which extinguishes all the green lights. If desired, an audible buzzer may be connected to the emergency switch.

The duplex convenience outlet furnishes a connection for portable electric devices such as examination or reading lamp, electric fan, etc. Two appliances may be connected to this outlet at the same time.

Notwithstanding that this is midsummer and vacation time, my sales are 100 per cent larger in the aggregate than they were at this time last year. I am striving to better the service that I give the physician in every way. If the physician is in the city, I can deliver the book desired in a few moments after the order is received. If the physician lives out of the city, the order goes forward by the very next mail.

Thirty years' experience in the medical book business entitles me to claim some knowledge of medical books. This knowledge and experience is always at your command.

Knowledge

*The attribute and useful tool
of the successful.*

Have you a knowledge of the savings and economy that can be effected by the use of your own laundry? If so, this message is not directed to you—it is for those who have not this knowledge. It is the desire of this corporation to assist those who do not operate their own laundry to a thorough knowledge of the benefits of this particular department.

Years of service in the planning of laundry departments for hospitals has given us a knowledge of the needs of such institutions that is yours for the asking.

We will not tell you that a laundry in your hospital will be an economy unless our survey proves that it will be. But we are interested in showing you the possibilities for saving if you can use such a department in your hospital.

Are you interested in gaining this knowledge? If so, write our nearest office.

FOR THE PATIENT WHO BALKS AT BRAN

ZED

The same patient who registers a decided dislike for bran gladly takes to ZED. For ZED is a delicious laxative biscuit in which the coarseness of the bran is hidden by the fine flavor of whole wheat.

In addition, milk, natural fruit and vegetable extracts are used in the blending of ZED to make it tasteful and appealing—and also to supply important mineral elements.

Thus the patient with a marked antipathy to bran finds himself with a marked liking for ZED. There is nothing in ZED to remind him of that "straw-like" taste he has mentally associated with bran. There is everything in ZED to make him like to eat the amount you advise.

We will be glad to supply to any physician on request a full-sized package of ZED for trial purposes.

The Dietetic Value of Gelatine

Receives High Recognition

The edition (6th) of "Diet in Health and Disease" by Dr. Julius Friedenwald and Dr. John Ruhrah, published by W. B. Saunders Company, Philadelphia, contains the following tribute to the value of Gelatine in feeding infants and children.

"JACOBI in 1879 suggested the use of Gelatine in infant feeding, and it has been used some ever since, but only recently has the real value of Gelatine in the diet been made more widely known. It is very useful in rendering milk mixtures more digestible, preventing both gastric and intestinal indigestion by preventing the large hard curds. Where the appetite is poor, the addition of Gelatine makes the milk more palatable for some children. It is of value in infants who regurgitate or vomit their food, in diarrhea particularly where there is putrefaction. It is useful where gas is formed, either in the stomach or intestines, and in fermentative conditions in general. It is useful in preventing colic in some babies, and in the breast fed may be given in solution just before feeding. In infants who are constipated and who have large hard stools which do not adhere to the napkin, the addition of Gelatine to the formula usually corrects the difficulty. It is of great value in celiac disease, not only in supplying additional much needed food, but in correcting the accompanying indigestion. In malnutrition the addition of Gelatine to the dietary is of great value, as it is in those who have lost weight through operations, fever, or other illnesses. It has also been suggested in scurvy."

Knox Sparkling Gelatine—highest quality for health—is the purest form of plain granulated Gelatine, produced by the most scientific methods, and under constant bacteriological and chemical laboratory control. It contains no artificial flavoring—no sweetening.

In prescribing Gelatine for the diet, physicians should be extremely careful to specify *Knox Sparkling Gelatine*.

FREE — TO PHYSICIANS AND HOSPITALS

The physician's reference book of nutritional diets with recipes will be sent free to physicians or hospitals, upon request, if they will address the Knox Gelatine Laboratories, 417 Knox Ave., Johnstown, N. Y.

In addition to the family size packages of "Plain Sparkling" and "Sparkling Acidulated" (which latter contains a special envelope lemon flavoring,) Knox Sparkling Gelatine is put up in 1 and 5 pound cartons for special hospital use.

KNOX

SPARKLING GELATINE

"The Highest Quality for Health"

BOOKS RECEIVED

All books received are promptly acknowledged in this column. Such acknowledgment is the only return California and Western Medicine feels obligated to render in return for the courtesy of the sender. Selected books believed to be deserving of comment will be reviewed solely in the interests of our readers. Our advertising columns are open to publishers of acceptable books for such further statements as they care to make.

Diseases of the Ear, Nose and Throat. By Harold Hays, M. D. Illustrated with 495 half-tone and line engravings in the text, and fifty-five full page plates, nearly all in colors. Philadelphia: F. A. Davis Company, Publishers, 1925.

Diabetes, Its Treatment by Insulin and Diet. A handbook for the patient. By Orlando H. Petty, M. D., and William H. Stoner, M. D. With illustrations and tables. F. A. Davis Company, Publishers, 1925.

Chirurgische Propädeutik. Eine allgemeine chirurgische Diagnostik für Studierende und Ärzte. Von Professor Dr. Erich Sonntag. Mit 135 Abbildungen im Text. Verlag von Georg Thieme, Leipzig, 1925.

Ergebnisse der Medizinischen Strahlenforschung (Roentgendiagnostik, Roentgen, Radium und Lichttherapie) Herausgegeben von H. Holfelder, Frankfurt a. M. H. Holthusen, Hamburg. O. Jungling, Tübingen. H. Martius, Bonn a. Rh. Band 1. Mit 451 Abbildungen in Text und 3 photographischen Tafeln. Leipzig, 1925. Verlag von Georg Thieme.

Conduction, Infiltration and General Anesthesia in Dentistry. By Mendel Nevin, D. D. S., and P. G. Puterbaugh, M. D. Second Edition. Illustrated with 210 engravings and large trifacial nerve chart. Dental Items of Interest Publishing Co., 1924.

Simplified Nursing. By Florence Dakin, R. N. J. B. Lippincott Co.

The Principles of Public Health Engineering. By Earle B. Phelps, B. S. The Macmillan Company, 1925.

The Newer Knowledge of Nutrition. The use of foods for the Preservation of Vitality and Health. By E. V. McCollum, Ph. D., Sc. D., and Nina Simmonds, Sc. D. Third edition entirely rewritten. The Macmillan Company, 1925.

Annual Report of the Board of Regents of the Smithsonian Institution showing the operations, expenditures and condition of the institution for the year ending June 30, 1923. Washington Government Printing Office, 1925.

Physical Diagnosis of Diseases of the Chest. By Joseph H. Pratt, M. D., and George E. Bushnell, M. D. Octavo of 522 pages with 166 illustrations. W. B. Saunders Company, 1925. Cloth, \$5 net.

The Normal Diet. A simple statement of the fundamental principles of diet for the mutual use of physicians and patients. By W. D. Sansum, M. D. Director of the Potter Metabolic Clinic, Department of Metabolism, Santa Barbara Cottage Hospital, Santa Barbara, California. The C. V. Mosby Company, 1925.

The Habit of Attending Medical Meetings— Presence at a meeting, hearing discussions and papers not only is of value to the beginner, but has been considered of importance to our masters, says Marcus Feingold, New Orleans (Journal A. M. A.). Naturally, not all that is transacted in every meeting is of the kind that signifies progress and betterment; some things presented may be of the kind that should be avoided and deprecated. But there is good also in listening to this kind because it teaches how to avoid the mistakes of others. Presence at meetings produces, in different members of the audience, various emotions. These emotions must apparently fall into one or more of the following subdivisions: admiration for the subject or the speaker; feeling of one's own inferiority in having done so little; the desire to imitate that piece of work and that method; the determination not to overlook this or that in the future, and regrets at having failed to observe this and that. Attendance at meetings has often led to ties of the most fruitful and warmest friendships among medical men the world over. History of medicine contains many records of the wonderful effects of exchange of thoughts among friendly spirits, just as these medical meetings. Attendance at meetings must not be limited to those of our immediate circles. The larger the group of individuals banded together, the greater is the probability of valuable and stimulating contributions at that meeting.

The Mechanical Part of Professional Service

Is often more important than you may consider it

ALL the skill and all the knowledge that you use in diagnosing refractive errors may avail your patient nothing if the mechanical work of the manufacturing optician does not measure up to the same high standard you set for yourself in your professional practice. Choosing the source of supply for your optical prescription work is therefore an important part of the service you render.

Grinding the Lenses

IN our mechanical work you can have the utmost confidence. Here we are specialists in every department of making glasses from grinding the rough blanks to delivering the finished product to your desk or to your patients. For twenty-five years we have been serving the profession and the profession only, and serving them so well that our clientele has grown with almost unbelievable rapidity.

Cutting and Edging

YOUR freedom from mechanical difficulties is assured when you send your prescriptions to a RIGGS house. Your best interests are our only concern, and if you are not already acquainted with the superior features of our prescription service, may we urge you to give us an early trial. Nothing we could say will be so convincing as an actual demonstration of our ability on your most perplexing cases.

Assembling the Finished Glasses

Wrapping for Safe Delivery

Step by step—Every safeguard, every precaution on every necessary operation of spectacle making, is taken to insure glasses in accordance with the prescription you write. Every detail of construction must pass not one, but many rigid inspections. Quality of materials and workmanship is the unbroken rule from start to finish.

SERVING ONLY REGISTERED REFRACTIONISTS

Radium and Oncologic Institute

1052 West Sixth Street

LOS ANGELES

RADIUM THERAPY

An adequate quantity of radium and complete emanation apparatus affords the facilities essential for modern technique in radium therapy.

DEEP X-RAY THERAPY

Two complete 300,00-volt installations providing every facility for preliminary and post-operative Radiation and X-ray Therapy alone or in combination with other treatment.

X-RAY DIAGNOSTIC LABORATORIES

Completely equipped offer the profession every assistance for roentgenology as an aid in diagnosis.

HOSPITAL AFFILIATIONS

Including a complete high voltage X-ray and Radium Therapy department in the Methodist Hospital amply provide for cases requiring hospitalization.

LABORATORIES

Affiliated for clinical and pathological study and complete facilities for Actinic Ray Therapy.

This institution possesses unexcelled facilities for radium and radium emanation therapy and high voltage X-ray therapy. With modern X-ray diagnostic, clinical and pathological laboratories, complete equipment for electric coagulation, cautery and allied surgery, it offers the medical profession unexcelled facilities for the diagnosis and treatment of neoplastic diseases.

We desire to confer and co-operate with the Medical Profession in the treatment of cancer and other appropriate diseases and request inquiries either in person or by correspondence.

J. W. Warren, M. D., Roentgenologist

E. D. Ward, M. D.

REX DUNCAN, M. D., Medical Director

Ivy Poisoning—The problem that has been studied by G. L. Krause and F. D. Weidman, Philadelphia (Journal A. M. A., June 27, 1925) has been that of the preventive phase of ivy poisoning and not of the cure of the already established disease. Therapeutics was the second phase of their work. The work done by the authors confirms that: The discharge from the lesion does not disseminate the disease; the virus itself must come in contact with the part. Susceptible individuals may contract ivy poisoning at any time of the year, provided the juice of the plant comes in contact with the skin. As new findings they report that: Repeated attacks tend to shorten all the stages of subsequent attacks. Local immunity is not developed by repeated attacks of ivy poisoning. There is such a thing as absolute (and probably permanent) immunity against ivy poisoning. In their series, two thirds of the men who believed themselves immune were not immune. In 45 per cent of the susceptibles it was necessary that some such defect in the epidermis, as scratches, should be present before a dermatitis would develop. It appears that all of the commoner laboratory animals are immune to this virus. Puritus ani, transient, appeared in the majority of those receiving preventive treatment; in two subjects, hemorrhoids were aggravated. The pain at the sites of intramuscular injections outweighs the danger of future attacks of ivy poisoning such as are only suppositious in the commoner walks of life. In their series of sufficiently controlled subjects, the preventive system of treatment of Strickler did not prevent; it is possible that the curative value of this system is likewise scant or nil, and that the beneficial results which have been reported are depended on and ascribable to the variable susceptibility of different individuals and the varying intensity of the irritant as applied at different times.

The death of Professor August von Wassermann on March 16, 1925, has deprived the medical world of one of its ablest investigators and the human race of a benefactor.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.

2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.

3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.

4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.

5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

SPECIAL ARTICLE

FOCAL INFECTION, A MEDICO-DENTAL PROBLEM. *

By F. P. WISNER, M. D., *Research Assistant, California Stomatological Research Group*

It is not often that the results of "research" are made so promptly available to and practically applicable by physicians in the promotion of health and the limitation and treatment of disease as is the work of Doctor Wisner and his colleagues discussed in this essay.

As is the case with most worthwhile investigations, much of the research embodied in this essay has been carried on in the library and these findings have been included with those of the author with a lucidity not otherwise possible.

This study has been made possible by grants from the Carnegie Corporation of New York, the American Dental Association, and the Associated Radiograph Laboratories of San Francisco.

There are thought-provoking messages here for every physician and every dentist.—EDITOR.

ORAL focal infection is an inseparable part of general focal infection.

The commonest primary lesions are teeth, tonsils, sinuses, and prostate.

Secondary foci may exist almost anywhere throughout the body.

The primary lesions are usually symptomless and need not yield pus, rendering them difficult to locate.

The remote effects are due to bacteria or their toxic products, transported by ways of the blood or lymph stream.

Streptococci are the commonest organisms concerned in focal infections, although others may be responsible.

Among the dental pathological conditions responsible for focal infections, periapical infections and pulpless teeth are of prime importance. Pyorrhea must also be considered.

The dentist is one of a group of specialists whose services are requisite to the proper diagnosis and treatment of a case of focal infection.

Local surgical treatment often requires to be supplemented by general measures, designed to build up bodily resistance against inaccessible foci.

infection. But the condition which is commonly termed focal infection is a transported infection of organisms of the staphylo-streptopneumococcus group.†

WE ARE living in a period when the condition of focal infection is finding its proper place in the science and practice of medicine and dentistry. There are those who would give it a place with tuberculosis and syphilis, as being one of the three most important of all infections. This is somewhat surprising in view of the short time which has elapsed since the condition was first described as a clinical entity. It has been estimated that over 60 per cent of all patients admitted to all our hospitals are sent in because of some manifestation of this condition. But it is only recently that we have had a sufficiently clear insight to realize that all these cases belong in the same category. Formerly they were considered to be totally unrelated conditions. And like all advances along the lines of correct classification of diseases, we find that this new conception of focal infection serves to greatly simplify our notions of many diseases, and to group together numerous conditions which were previously considered to be totally dissimilar. Likewise, several conditions previously thought to be tuberculosis, are now recognized as being manifestations of focal infection.

WHAT THEN, IS FOCAL INFECTION?

It may be defined as the transportation of infection from one portion of the body to another, with an infection resulting in both places. Thus, a periapical abscess may give rise to an arthritis. But, according to this definition, we might place syphilis, tuberculosis, and in fact, all the infectious diseases we know, in this same category. And the truth of the matter is that, broadly speaking, all these diseases are types of focal

THERE ARE MANY TYPES OF FOCI

First of all, there is the active focus, or the one which is responsible for acting as a source of infection for the rest of the body. There is then, the inactive focus, which, although harboring infection,

* Aided by grants from Carnegie Corporation of New York, American Dental Association, and Associated Radiograph Laboratories of San Francisco.

† The great majority of the organisms isolated from infected extracted roots of teeth in our clinic, by Mrs. Pauline Scott, have been members of the strep-veridans tribe.

is not guilty of metastasizing. It is, however, a constant menace, due to the fact that it may, at any time, and without any warning, become an active focus. There is the primary focus, which is located in the mouth or in one of the body's other readily accessible cavities. This is the initial focus of the infection in the body and serves as a breeding place and center from which organisms may be discharged to all parts of the body. Then, there are secondary foci, which are located anywhere throughout the body, and become infected with organisms transported from the primary focus. The secondary foci may, in turn, become primary foci; that is, they may themselves become sources of infection for other parts of the body.

With respect to the speed with which secondary foci are established, we may distinguish between acute and chronic focal infections. In the acute focal infections, the secondary foci appear very soon after the establishment of a primary focus. Usually the time interval is so short that they appear to exist coincidentally. Examples of acute focal infection are the development of an acute osteomyelitis or perinephritic abscess following a boil on the skin, the incidence of an acutely suppurating joint following an acute tonsillar or periapical infection, and so on. Due to the acuteness of both primary and secondary foci, it is evident that these cases are much more readily diagnosed than the chronic cases. In cases of chronic focal infection, the primary focus precedes the secondary focus by months or perhaps years. The primary focus gives few if any clinical evidences of infection, while the secondary focus is not nearly as acutely involved as in the cases of acute focal infection. There is, thus, little in the secondary focus and possibly nothing whatsoever in the primary focus to call our attention to the infectious nature of the process. The difficulties of diagnosis in these chronic cases is thus readily apparent and will be emphasized later. It is with the chronic cases that we will concern ourselves in this discussion, since the acute cases are readily diagnosed, and their treatment apparent.

The common primary foci in the body are: 1, Periapical abscesses; 2, Pulpless teeth; 3, Paranasal sinuses; 4, Tonsils and adenoids; 5, Prostate and seminal vesicles; 6, Skin. It will be noted that all of these foci are located in cavities situated close to the surface of the body.

The common secondary foci are: 1, Regional lymph nodes; 2, Joints; 3, Tendons, ligaments and fascia; 4, Nerves and brain; 5, Appendix and gall bladder; 6, Kidney; 7, Heart muscle; 8, Eye and ear; 9, Stomach and intestine; 10, Lungs. It is readily apparent from this, that there are few spots within the human body which are immune to the inroads of focal infection.

The methods by which the distant effects of focal infection are produced vary considerably. The commonest method is by the lymphatic transportation of the bacteria. This is often the cause of swollen and infected glands of the neck, resulting from infection in either the teeth or tonsils. Another common method by which the bacteria may be transported is through the blood vessels. Certain conditions, as neuritis, are thought to be due to the dissemination of toxic products of bacterial

activity, rather than to the transportation of the bacteria themselves. This toxic absorption takes place, of course, either through the venous or lymphatic channels. A means of transporting infection, which has as yet not received very serious consideration, is the swallowing of bacteria and their toxic products, from foci existing in the mouth or pharynx. This lack of consideration is due to the assumption that bacteria and their products would be neutralized and destroyed by the action of the gastric juice. Thus, we see, that the first three named methods of spread are by far the most important, namely: 1, Lymphatic spread of bacteria; 2, Blood-borne bacteria; 3, Toxins borne by blood (or lymph).

In considering the factors which predispose toward the localization of an infection, we are striking at the heart of the whole question of infection and immunity. As was already indicated, the primary foci are located either on the body surface, or else in one of the readily accessible cavities adjoining the body surface. Factors favoring the establishment of an infected primary focus, are the same identical factors which predispose to infection anywhere, namely: 1, Weakness resulting from previous infection (ex. prostate); 2, Mechanical defects (ex. nasal septum); 3, Trauma (ex. prize-fighter's wrists); 4, Exposure to cold; 5, Poisons of all sorts; 6, Deficient blood supply (ex. joints); 7, Senility, fatigue, starvation, etc. Here, as in all types of infection, the establishment of an infectious process depends on: 1, The dosage of organisms; 2, The virulence of the organisms; 3, The resistance of the host.

The streptococci seem to be one of the most versatile of all organisms, being able to adapt themselves to a great variety of environments. When once they have localized in a particular region, due to a combination of the above mentioned factors, they develop a tendency to become specific for that particular organ, as is shown by their behavior when injected into animals. If, for example, as Rosenow has shown, a strain of streptococci recovered from the apex of an infected tooth in a patient suffering from, let us say, gall bladder disease, are injected into a series of rabbits, the great majority of the lesions produced in the animals will be gall bladder infections. This principle of elective localization is not a new thing in our experience. We have witnessed it previously with a great variety of diseases, such as mumps, gonorrhea, whooping cough, and many others—and yet it has been difficult for many to accept this same fact when applied to the streptococcus. Another factor which seemingly influences the virulence and also the localization of the streptococci, is that of oxygen tension. They prefer a lower oxygen tension than exists on the surface of an exposed mucous membrane, and under conditions of lowered oxygen tension, tend to become increasingly virulent. Thus, the virulent streptococci are found lurking in out-of-the-way corners, as deep in the tonsillar crypts, in the periapical tissues, in the paranasal sinuses, in the prostatic ducts, etc.

A consideration of prime importance is the fact that these lesions, dental and otherwise are almost invariably painless. This fact often adds to the

difficulty in persuading an already reluctant patient to have the focus eradicated. It also doubtless often causes the operator to hesitate and speculate about the advisability of removing a silent focus. Another common misconception is that an infected focus should manifest itself by the production of pus. It is general knowledge that the streptococci are organisms which commonly do not produce pus. On the contrary, the type of exudate which they usually provoke is more serous in character. Hence the apparent folly of refusing to remove tonsils on the ground that pus cannot be expressed from them.

This brings us to a consideration of the means at our disposal of diagnosing chronic focal infection. To begin with, let us state that these are quite unsatisfactory. First of all, the patient presents himself before us with a condition commonly known to be caused by focal infection—an arthritis, neuritis, nephritis, gastric ulcer, myocarditis, iritis or possibly a severe anemia. There are very few tests of a general nature that we may apply to determine the existence of chronic focal infection, and these are by no means generally accepted as valid. The blood picture, it is claimed by some, is quite typical. This consists of a decrease in the total number of white corpuscles, of polymorphonuclears, and of red corpuscles, together with an increase of the lymphocytes. A rise in the blood's content of uric acid is also claimed to be due to focal infection, provided none of the more obvious causes of high uric acid are formed. It is also claimed that upon removal of all foci, the uric acid content of the blood returns to normal. Thus, it will be readily seen that while the diagnosis of acute focal infections is easy, due to the fact that the local and general symptoms are clear-cut; in chronic focal infections our attention is drawn mainly to the secondary focus, while the primary focus is silent, and there is little of certain value in the patient's general condition to give us a clue as to the nature of his trouble.

In searching for possible primary foci, let us begin with the mouth. As far as the teeth are concerned, there are two conditions with which we are particularly interested. First is the chronic periapical abscess, or granuloma. The method most depended upon to locate these is by means of the radiograph. It is needless to state that several pictures should often be taken from different angles in order to discover apical lesions, especially in the molar teeth, where they are apt to be obscured by bony processes. The other type of tooth in which we are especially interested is the pulpless one. It seems to be the current opinion that between 50 and 80 per cent of pulpless teeth are infected. Even if uninfected the pulpless tooth is a constant liability, since it may, at any subsequent time, become infected. The burden of proof against this statement, it would seem, rests upon the advocates of root canal therapy. Fortunately, there is a constantly decreasing number of teeth being devitalized, so that in the future, this particular phase of the problem will not loom as large as it does at present. Of practical importance is the fact that rarely are teeth suspected without being found infected upon extraction. It will be noted that there is a noticeable lack of condemnation of pyorrhetic teeth in this connection. This is

because mild degrees of pyorrhoea are considered to be lesions with good drainage, and thus with a minimum opportunity for absorption. However, we have reason to believe that a considerable number of pyorrhetic teeth develop infected pulps and periapical infections. In this event they are as dangerous from the standpoint of focal infection as a periapical infection in any other tooth. Probably more attention should be paid to pyorrhoea in examining the teeth of these cases.

There are certain writers who attribute cures to the removal of teeth which, they state, were negative radiographically. Just what we are to infer from this is a matter of conjecture. These men may be referring to non-vital teeth, calling them radiographically negative because they show no visible periapical absorption. We have already seen how non-vital teeth are to be suspected regardless of their radiographic appearance. Again, these authors may have been dealing with teeth bearing periapical abscesses which were unobserved, either because of their small size or because of their position. It is possible that these teeth may have been affected with pyorrhoea and that deep down, near the pockets, were small areas of infection that were walled off, and thus not provided with drainage. There is also the possibility that, unknown to the dentist, some other focus has been removed at about the same time as the removal of these apparently normal teeth. And lastly, there is the possibility that there is a type of infected tooth with which we are as yet unacquainted, and which our present methods of diagnosis cannot reveal.

We will not consider in detail the methods of diagnosing primary foci elsewhere in the body. Needless to state their determination requires the most careful efforts of the specialists in whose field they occur. Repeated nasal examinations are often necessary in order to determine sinusitis, and we have frequent occasion to resort to radiographs and the washing out of the sinuses for diagnostic purposes. Infected tonsils may appear entirely healthy, but upon culturing the excised organs we will find virulent bacteria. Similarly an infected prostate or seminal vesicle may feel absolutely normal to the palpating finger, but upon repeated massage, will be found to contain an infected secretion. Thus, the study of a case of focal infection, as will readily be seen, is a problem which calls for the combined efforts of the clinician, roentgenologist, dentist, rhinolaryngologist, urologist, and probably other specialists. Such co-operative efforts are best directed by the clinician, who, alone, is in a position to consider the case as a whole, and to decide upon the basis of the evidence obtained, what the proper sequence of treatment shall be. The place of the dentist in such a scheme of things is apparent. He ranks with the other specialists, being the one whose duty it is to locate and subsequently eradicate infected teeth and investing tissues.

As an aid in locating the primary foci in a given case, it has been suggested that an over-dosage of an autogenous vaccine would cause such an acute exacerbation of the infectious process that the primary focus would be temporarily changed from a chronic to an acute focus. This would serve to bring it to the direct attention of the patient and

his attending clinician. This is possibly a wise procedure in those obscure cases where we feel confident that there are primary foci which we have been unable to locate. As a routine procedure, however, we can hardly at present recommend it. In the lack of an autogenous vaccine, it is possible that a slight overdosage with parathyroid extract would produce similar results.

We are now ready for a consideration of the proper treatment of a case of focal infection. Having located as many primary and secondary foci as we are able, we proceed with their surgical removal; that is to say, the removal of all the accessible foci. Where both teeth and tonsils are involved, it is claimed that better results are obtained if all the infected teeth are removed before the tonsils are excised. For the removal of teeth with periapical infection, the consensus of opinion seems to be in favor of Shearer's method of external alveolectomy, since it facilitates the complete exposure to view of the infected area. The extraction of large numbers of infected teeth at a single sitting, in these cases, is not the wisest procedure, because of the possibility of causing a violent flare-up of all symptoms. And in that connection it should be said, that probably the cases in which a flare-up is caused, are the ones which will be most benefited by the eradication of the infection. It is often important to reassure the patient by pointing out to him this fact, lest the exacerbation should prompt him to abandon treatment. In regard to the extraction of teeth, nothing is a more reprehensible mode of procedure than for the physician to order all the patient's teeth out merely on the suspicion that some of them are infected. There are many cases when complete extractions are indicated, but it is the blind and ruthless ordering of wholesale extractions which we are condemning. After the dentist has removed the infected teeth, and reconstructed the mouth for mastication, the clinician should see to it that all other accessible foci are likewise removed, be it tonsils, sinuses, prostate, gall bladder, appendix or what not. The removal of these infections depends, of course, upon their location, and often is not nearly so practical as the removal of dental infections.

In conjunction with the removal of accessible foci, we often have occasion to resort to local treatment in the region of the secondary focus. For example, in case of a joint involvement, we supplement the removal of foci with casts applied to the joints, followed by bakes and massages. In case of an iritis, we dilate the pupil with atropin and rest the eye by bandaging it shut. Naturally, this subsidiary treatment varies with the location of the secondary foci; the general principles involved being rest from function and the stimulation of hyperemia.

There are certain conditions, let us take for example, syphilis and tuberculosis, which, although entirely separate etiologically from focal infection, nevertheless are benefited by the removal of foci. This is readily explained by assuming that the body is relieved of an added load, and that it is thus rendered better able to fight the uncomplicated syphilitic or tuberculous infection than when a focal infection coexisted. In this connection, the prophylactic

removal of foci of infection, wherever found, should be urged. The fact that the foci are inactive and that secondary foci have not yet been established, does not mean that such inactivity will continue indefinitely. The lack of secondary foci may be due to the fact that the lesion is draining freely (as in the milder degrees of pyorrhoëa), or to the fact that the body has been able to wall off the infection, or that the patient has sufficient immunity to prevent the re-establishment of secondary foci. It is evident, however, that none of these conditions are necessarily permanent; that is to say, they are not a guarantee against subsequent systemic involvement. The old adage concerning an ounce of prevention is just as apropos here as elsewhere. Prophylaxis is just as important in the field of focal infection, as in any other diseased condition.

Due to the fact that many foci are inaccessible or difficult to clear up, we have occasion to supplement our local treatment of foci with general measures, whose purpose it is to build up bodily resistance to the point where the body can overcome what infectious foci we are forced to leave within its tissues. It is in this field that the future's great promise lies, as far as the treatment of focal infection is concerned. Measures which we may employ in the hope of accomplishing the above mentioned results are: Autogenous vaccines, ultra-violet light, Roentgen rays, and parathyroid extract. The goal of our ambitions would be reached were we able to dispense with the surgical removal of foci and devote our entire attention to the administration of these resistance-building agents. However, in our present state of knowledge, we are forced to rid the body by surgical means of as much of the load of infection as lies within our power, and to supplement this local treatment with general measures directed toward the building up of resistance against the remaining inaccessible foci.

[Since above was received for publication, Doctor Wisner, still working under the original grant and association, has carried his work further, as shown in the subjoined brief article.—EDITOR.]

A COMPARATIVE STUDY OF THE GENERAL SYSTEMIC AND DENTAL CONDITIONS OF FOURTEEN DENTAL STUDENTS*

By DR. F. P. WISNER, M. D.

The etiology of periodontoclasia still lies in obscurity. There are those who urge that purely local factors are wholly responsible for the condition. On the other hand are the men who blame systemic factors. There are doubtless many who adhere to a middle course, agreeing to some extent with both extremes.

This work was undertaken in the hope that it might help to solve this problem of the etiology of periodontoclasia. A group of dental students in their junior year were selected as subjects for examination. They were chosen for a number of reasons. In

*Aided by grants from the Carnegie Corporation, the American Dental Association, and the Associated Radiograph Laboratories.

the first place, it was felt that these young men would more willingly co-operate with our efforts if the object of our study was explained to them. In the second place, it was felt desirable to pick young subjects, since in young persons we would be more apt to find pure disease entities, uncomplicated by the many factors which appear during advancing years.† In return for the privilege of studying these patients, we were able to offer them the advantages of a thorough dental and medical examination, along with any appropriate advice and treatment that was deemed merited.

The dental examinations were made by Dr. Clayton Westbay, and were aimed particularly at the detection of early stages of gingivitis.

The medical examinations were made by the writer, and were of the same character as the average patient entering the University of California Hospital receives. Any abnormalities found were then followed up in more detail, and free recourse was made to the opportunity of consulting specialists, especially in the field of rhinolaryngology. Particular attention was paid to the determination of the existence of all foci of infection, almost all the cases being submitted to nose and throat examination and prostatic massages. Blood Wassermans were run on all the subjects, and in each case the urine was submitted to routine examination. It was hoped to obtain a complete blood count on all the cases, but we were unfortunately unable to secure the technical assistance.

In the table are listed the presence and degree, or absence of both caries and periodontoclasia. Both active and healed conditions are noted. From the medical standpoint all abnormalities, however trivial, were recorded, in the hope that some correlation might be possible. Only the abnormal medical findings are indicated.

Age		Caries	Periodontia
J. E. 22		+	+
T. D. 24	Deviated nasal septum	+	+
R. G. 24	Gassed in France	+	+
E. V. 22	Slight emphysema	+	—
F. T. 26	Acne	+	+
N. C. 21	Infected tonsils, thickened nasal septum	—	—
E. H. 29	Baldness, infected tonsils, inguinal hernia	+	+
L. O. 24	Baldness, infected tonsils, deviated nasal septum	—	+
W. B. 26	Asthma, hay-fever, cholecystitis	—	—
W. B. 28	Constipation, chronic appendicitis, cervical lymphadenopathy, pulmonary tuberculosis (?)	+	+
T. D. 33	Moderate baldness, acne, arterial hypotension, herpes progenitalis, infected tonsils	+	+
D. A. 21	Amebic dysentery, cervical lymphadenopathy	+	—
M. S. 31	Moderate baldness, orthostatic albuminuria, lordosis	+	+
B. T. 20	Acne, arterial hypotension, gastric ulcer (?)	+	+

Note: — means free from caries or periodontoclasia, while + means presence of either of these diseases. The number of + signs indicates, roughly, the degree of involvement.

† As will be noted by reference to the table, the ages of the men examined ranged all the way from 20 to 33.

A study of the foregoing table reveals several interesting facts. In the first place, the patients with few medical defects may or may not have dental disease. The one patient in whom no medical defects were noted had a certain degree of both caries and periodontoclasia. Secondly, those patients who had a greater number of medical defects, showed no uniformity in the degree of dental involvement. Studied from the dental standpoint, there seems to be no correlation between caries and medical defects. In regard to periodontoclasia, the only possible significant fact that we can discover is that all but one of the cases showing a moderate or severe degree of periodontoclasia show also some type of dermatological involvement. This was acne in some cases, and partial baldness in others. One of the cases showing only a mild degree of periodontoclasia had a severe case of acne. All the other cases with mild or without periodontoclasia, showed a healthy skin in all respects.

This connection between periodontoclasia and dermatological diseases, while rather striking in this small series of cases, may be a mere coincidence. On the other hand, it may be a matter of great significance. This series of cases is too small for any lengthy deductions to be drawn. We, therefore, recommend to those who are interested in the etiology of peridental disease that they make note of any concomitant dermatological diseases, in order that a large enough series of cases may be recorded.

Pernicious Anemia, Following Ileostomy—The absorption of hemolytic, myelotoxic or neurotoxic material from the contents of the small or large intestine has been regarded as more than a plausible possibility in pernicious anemia because of the prominence of gastro-intestinal symptoms, the atrophy of the gastric and intestinal mucous membrane, and the occasional association of pernicious anemia with intestinal stricture and also parasitic disease. This belief led C. F. Dixon, J. G. Burns and H. Z. Giffin, Rochester, Minn. (Journal A. M. A.), to the decision that, under favorable circumstances, they would recommend temporary elimination of the colon by means of ileostomy in cases of pernicious anemia, with a view to the determination of the influence of colonic absorption on the course of the disease. Ileostomy may be performed with minimal risk, and, should prolonged improvement occur, ileosigmoidostomy could be performed later, not removing the colon, but excluding it as a mucous tube. Six cases are reported. The patients have all shown the temporary improvement that so frequently follows any treatment for pernicious anemia. All have maintained a good appetite, even with the recurrence of anemia. They all lost the icteroid tint, and it did not reappear even in those who later became anemic. Glossitis recurred in only one case when irrigation of the colon became difficult, and this disappeared in a few days after the colon could be flushed. Probably the most striking feature has been the disappearance of paresthesias in all but one case, in which there was very marked improvement. This patient had moderately advanced cord changes and walked with extreme difficulty; even so, the paresthesias have not been troublesome since ileostomy, and the patient is able to walk without assistance. One patient showed slight improvement objectively and on neurologic examination. Two patients of the series died from conditions unrelated to pernicious anemia. Two have done unusually well. Two have had a recurrence of the anemia. One patient, who had very marked manifestations of the disease, has been in excellent condition for eleven months. Ileostomy cannot at present be advocated as a therapeutic measure, but in small groups of cases it is justifiable until its effect is definitely known. The procedure alters certain features of pernicious anemia, and may lead to more important results.

TREATMENT OF POISON OAK DERMATITIS*

By HARRY E. ALDERSON, M. D., San Francisco

INTRODUCTORY NOTE

Poison oak and similar contact skin poisons are exceedingly prevalent seasonally over wide areas of our Western country. Every physician and every citizen is anxious to see improvement in our methods of prevention and treatment.

Doctor Alderson and Doctor Donald have devoted much time to a study of the problem and presented their findings at the recent session of the C. M. A. in Yosemite National Park. Because of the wide interest in poison oak dermatitis, publication of this paper is advanced to meet the seasonal incidence of the disease.—EDITOR.

Discussed by W. G. Donald, Berkeley.

SINCE 1918 I have been using an alcoholic extract of the poison oak plant (*rhus diversiloba*), by intramuscular injection and oral administration in the treatment of active poison oak dermatitis and for immunization against the same. Extensive experience convinces me that this specific therapy is better than any other treatment so far developed.

The idea is not new. For years before the pioneer work recorded by Schamberg, Strickler and myself, our California Indians and Mexicans had been eating leaves of the plant to develop immunity. Old settlers testify that this method, crude as it was, produced good results. Severe inflammation of the upper alimentary tract sometimes occurred, however, and at times the "cure was worse than the disease," for fatalities resulted. This method is still being resorted to by natives.

Before taking up the specific poison oak extract treatment, local therapy will be discussed briefly. The poisonous element in the poison oak and poison ivy plant is toxicodendrol, a non-volatile glucoside. A very minute amount of the poison, well diluted, will produce dermatitis. Treatment of dermatitis venenata always has consisted, first, of attempts at removal, or neutralization, of this poison. This is accomplished to a certain extent by washing thoroughly and repeatedly with soap and alkaline solutions, followed by alcohol. Unless the alcohol is used very thoroughly, however, it may spread the poison. If the entire skin and hair is washed in running water, shortly after exposure, and if every article of wearing apparel worn at the time is thoroughly cleaned, the disease may be prevented or greatly ameliorated. If an aqueous solution of potassium permanganate is applied early it may oxidize the toxicodendrol, thus neutralizing its effects. This method has the objection that skin and clothing are stained. I have had patients who carried soda solution with them when working in the poison oak and who, by frequent bathing of exposed parts with this solution, warded off attacks. This procedure is very inconvenient and forgotten contaminated clothing may later produce the dermatitis.

After the inflammation has developed, alkaline lotions, containing antipruritics and a soothing powder in suspension, are useful in ameliorating the local symptoms. Ordinary calamine lotion is good, but one consisting of one per cent menthol and phenol, and 10 per cent zinc oxid in lime water, is

more generally useful. Epsom salts solutions (hot or cold), and baths, may give a great deal of relief. As dermatitis venenata lesions are often secondarily infected, naturally toxin treatment has no effect on this complication and antiseptic solutions are indicated. Bullae should be opened under aseptic conditions. It has been proved that the contents of the bullae are not irritative, so one need not fear that the serum will spread the disease.

Doctor William Donald, of the University of California infirmary, has developed an interesting method of local treatment. It consists of the local use of liquid air, which gives immediate and lasting relief from the itching, if applied sufficiently. He has also had considerable experience with the specific treatment which I have asked him to present at this meeting in opening the discussion of my paper.

In observing the progress of a case of dermatitis venenata one must bear in mind that persons vary greatly in their resistance to the poison. Tolerance for toxicodendrol varies, too, from time to time, in the individual. Furthermore, persons with seborrhea, or whose skin, for some other reason, is lacking in resistance and in ability to recover promptly from an injury, are apt to be more troublesome than the average patient. They may present an eczematous process (not true dermatitis venenata) that will persist long after the toxicodendrol has been eliminated. Seasonal recurrences of this eczema may be experienced in these areas of lessened resistance and be mistaken for dermatitis venenata.

We have all had patients presenting this eczema and believing that it is a recurrence of the old poison oak dermatitis without there having been exposure to the plant. Skins of this sort heal slowly. The process of keratinization may be unduly prolonged. Then the patient is apt to assume that it is the result of the poison oak toxin still acting, which is not the case. It is well known that the processes of repair in skin that has been severely damaged, as it is in poison oak dermatitis, may be delayed in those whose skins show an inherent tendency to develop eczema after injury. Such individuals make poor industrial risks.

The appearance of new lesions from several days to a week after the onset of the trouble was formerly attributed by some to irritating qualities of serum from the vesicles, and bullae. This has been proven to be wrong. Others thought the occurrence was due to systemic dissemination of the poison causing outbreaks in remote parts. It is now explainable on the basis of the varying penetrability of the skin. In some areas the poison may take from several days to a week to penetrate sufficiently to produce a specific dermatitis. These areas vary in individuals and in the same individual at different times. They result, probably, from lessened concentration of the deposited poison or from actual lessened vulnerability of the skin in said areas.

A great advance in dermatitis venenata therapy was made when Schamberg, in 1917, and Strickler, in 1918, presented the results of their work with the *rhus* toxin in cases of poison ivy dermatitis. In 1920 and 1922, Alderson recorded his experience with this method in the treatment of poison oak dermatitis at the Letterman General Hospital,

*Read at meeting of California State Medical Association, May 1925.

Presidio, San Francisco, at Stanford Medical School, and in private practice. This method has had such extensive use that its value is now generally recognized. Reports of physicians from all over the Pacific Slope prove its efficacy.

Doctor Carl Jones, (Grass Valley, California), writes that he has "treated about seventy-five cases of poison oak dermatitis with the poison oak extract with unusual success. The dermatitis usually cleared after two injections and he rarely had to use a third dose. Two or three treated patients developed recurrences which were promptly relieved by one injection. One instance was cited, that of a wood-chopper who was a frequent sufferer every summer, and was relieved by two treatments. Since then he has not had a single attack although he works and sleeps in the woods all the time. No untoward effects, or bad results, have been experienced at any time.

Doctor M. L. Fernandez, (Pinole, Contra Costa County), has had many cases, as the poison oak plant grows abundantly in his section. His records show that prior to 1921 when only local treatment was administered, the period of disability of employes suffering from poison oak dermatitis averaged about thirty working hours. Since 1921, when the use of poison oak extract was started by him, the period of disability has averaged about twelve working hours. Many cases now show no disability, the disease being relieved promptly by the poison oak extract. He has records of 114 cases.

Doctor U. S. Abbott, of Richmond, California, writes that he has treated at least fifty cases, the severe ones responding most satisfactorily. None had more than three injections, the majority receiving two. There were no untoward reactions and the results were always good.

At the "Round Table Discussion" of the American Dermatological Association meeting in June, 1924, the following discussion of the subject took place:

Doctor Jay F. Schamberg recounted his experiences, stating that he had treated over 100 patients with the toxin by mouth, with only favorable results. For immunizing purposes he uses the same method. When the toxin was used in advance, he failed to see any trouble during the poison ivy season. He believes that this protection does not last longer than a month. In treating a patient during an attack, he increases the dosage more rapidly than when it is used as a prophylactic.

Doctor Udo J. Wile indorsed Doctor Schamberg's statement and said that he had treated a number of patients with the rhus toxin and had never failed to give relief. He gives one dram three times daily.

Doctor Oliver Ormsby stated that he had had the same favorable experiences. He mentioned a patient, who was formerly very sensitive to poison ivy, but who later kept free from trouble by taking the immunizing treatment.

Doctor Howard Morrow reported that he had gathered a lot of poison oak and poison ivy and had used the preparation in many cases. Some of the patients had the worst attacks of dermatitis that they had ever had while taking his preparation. He stated that he was convinced that it had some

value and that he was still using it, but does not believe that it prevents attacks.

Doctor H. N. Cole reported very favorable results, citing several cases. He uses the poison ivy preparation regularly.

Doctor Fred Wise reported "uniformly good results" from the treatment.

Doctors Walter Highman and Jay F. Schamberg expressed the opinion that, possibly, in some cases, the dosage may be too large.

A review of my last hundred cases revealed some interesting facts. The histories are classified under three headings: (1) "favorable," (2) "unfavorable," and (3) "doubtful" or "incomplete." Those classed as "favorable" showed prompt, definite response and recovery following the poison oak toxin treatment. There were eighty such cases (80%).

Eight of the "unfavorable" cases presented conditions and factors which, by a liberal interpretation, might justify placing them in the "doubtful" or "incomplete" class, or in the "favorable" class. For this reason these eight records are given in detail:

No. 8553. A neurotic woman, 32 years old, had poison oak dermatitis of one week's duration. Injected 1 cc. poison oak toxin (concentrated). The patient fainted and it took some time to resuscitate her. One week later she returned, stating that the condition had not been relieved and that the areas were still intensely itchy. A soothing alkaline lotion was also given. The dilute solution was not given by mouth. We feel that another injection along with the specific therapy would have been beneficial.

No. 8693. A young woman always very susceptible to "poison oak," had an extensive acute dermatitis of several days' duration. She was given one injection of 1 cc. of the toxin, and the dilute solution to take internally. A soothing alkaline lotion was also prescribed. Three days later the patient was still in bed, showing no improvement, and we did not hear from her after that. Possibly a second injection would have given better results.

No. 8694. An adult male, always very susceptible to poison oak, had extensive acute areas of dermatitis, due to exposure two days previously. The usual 1 cc. injection of concentrated toxin was given and the dilute solution ordered by mouth and an alkaline lotion for local use. Two days later the condition was more acute and itchy. A second injection was given. The patient did not return.

No. 10481. A young woman had acute dermatitis venenata involving the neck and right forearm following exposure to poison oak one day after being in the country. She was given the dilute toxin solution only, and the usual alkaline lotion for local use. The condition improved slowly, clearing up in about two weeks. We believe that injections would have given much better results.

No. 10969. A young boy had acute dermatitis venenata on his face, arms and legs of four days' duration, appearing three days after exposure. The injection was objected to, so the dilute solution was given by mouth. Within three days improvement was observed, but it was almost a month before he had entirely recovered. Probably injections would have given a good result. He used also a soothing alkaline lotion.
